

## Ongoing Living Update of Potential COVID-19 Therapeutics: summary of rapid systematic reviews

**RAPID REVIEW – April 22<sup>nd</sup>, 2020.**

**(The information included in this review reflects the evidence as of the date posted in the document. Updates will be developed according to new available evidence)**

### **Disclaimer**

This document includes the results of a rapid systematic review of current available literature. The information included in this review reflects the evidence as of the date posted in the document. Yet, recognizing that there are numerous ongoing clinical studies, PAHO will periodically update these reviews and corresponding recommendations as new evidence becomes available.

## Ongoing Living Update of Potential COVID-19 Therapeutics: summary of rapid systematic reviews

### Background:

The ongoing COVID-19 disease pandemic (caused by SARS-Cov 2), with associated mortality and morbidity, has prompted a focus on the efforts to develop vaccines and treatments<sup>1</sup>. While the clinical presentation of COVID-19 ranges from asymptomatic to fulminant and fatal, severe cases of infection can develop pneumonia, acute respiratory distress syndrome, sepsis and/or multiple organ failure which are not unique to coronavirus<sup>2</sup>. Pulmonary failure can be considered the principle cause of death related to COVID-19 disease. The current standard treatment guidelines for COVID19 include pharmaceutical and other supportive care treatments<sup>3</sup>.

The scientific community has focused on developing and/or repurposing medicines that can target SARS-Cov 2 and help control the pandemic of COVID-19. Repurposing currently available medicines against COVID-19 has led to the development of hundreds of trials worldwide. Therapeutics under investigation include various antiviral and immunomodulatory medicines; the antimalarials chloroquine and hydroxychloroquine; corticosteroids; convalescent plasma; stem cells; pharmaceuticals targeting the renin-angiotensin system; hyperbaric oxygen and nitric oxide, among many others<sup>4</sup>.

The vast amount of data that will be coming will present important challenges and it must be interpreted quickly so that the correct most optimal treatment decisions can be made with as least harm to patients, and that manufacturers and supply chains can scale up production rapidly. This will ensure that reportedly successful drugs can be administered to as many patients and in as timely a manner as possible. Moreover, if evidence indicates that a medication is potentially sub-optimal and not effective, then the many ongoing clinical trials could change focus and pivot onto more promising alternatives<sup>4</sup>. Additionally, many are using drugs already in huge volumes and also via compassionate or single use applications<sup>5</sup>. It is absolutely imperative therefore that prescribers be given the most updated research evidence fast to inform if what was done was optimal or if it is not optimal or even harmful to patients. The following evidence-database was compiled to orient the published studies thus far and will endeavour to add to this table list as research is released into the public space. The drugs currently under review are: meplazumab, ivermectin, siltuximab, danoprevir,

tocilizumab (IL-6), favipiravir, darunavir, nelfinavir, remdesivir, interferon-alpha, chloroquine or hydroxychloroquine, convalescent plasma, heparin, corticosteroids, umifenovir (arbidol), and lopinavir/ritonavir.

## Methods:

MEDLINE and EMBASE electronic databases were searched from 2020 to present (April 22, 2020) using a mix of keywords such as COVID-19 and respective drug names, along with any relevant variants. The search did not use a randomized controlled trial filter. For example, the COVID-19 terms were ‘exp Coronavirus Infections/ or exp Coronavirus/ or exp Severe Acute Respiratory Syndrome/ or exp SARS Virus/ or coronavirus.mp. or severe acute respiratory syndrome coronavirus 2.mp. or 2019 nCoV.mp. or 2019nCoV.mp. or 2019 novel coronavirus.mp. or new coronavirus.mp. or novel coronavirus.mp. or SARS-CoV-2.mp. or SARS CoV-2.mp. or COVID 19.mp. or COVID-19.mp. or COVID19.mp.’ The decision was to also search by a specific drug name under study.

PubMed was also searched daily during this period as a means to gain a rapid assessment of any emergent publications. Searches were conducted daily from March 15<sup>th</sup> to present to uncover any new evidence. Evidence was considered from additional sources such as manuscript reference lists, clinical trials registers (such as the International Clinical Trial Registry Platform) and online trial portals that pre-publish studies not yet having completed the peer-review process. For example, we have searched and will continue to search the largest clinical medicine preprint repository, medRxiv.org, on a daily basis.

The focus was any types of comparative effectiveness research (ideally RCTs studies) for all of the included therapeutic pharmacological interventions (adults and children) and this review was open to any study that could be informative, including case-series and observational designs. Adults and children exposed to or with confirmed or suspected COVID-19 were and will be included. Trials that compare interventions head-to-head or against no intervention or placebo is the focus. We have focused on comparative effectiveness studies that provide evidence on patient-important outcomes, but were open to all reported outcomes at this time<sup>6</sup>. No electronic database search restrictions were imposed. If meta-analytical pooling was and is possible from retrieved evidence, this review would seek to do this to derive more precise estimates of effect and derive additional statistical power.

A risk of bias assessment was applied to RCTs as well as observational studies focusing on randomization, allocation concealment, blinding, attrition, or other relevant biases to the estimates of effect, as well as selection bias, residual confounding bias, statistical adjustment, matching (propensity score), stratification, or restriction, respectively<sup>7</sup>. The GRADE ‘outcome-centric’ method was applied to individual outcomes per study to derive a certainty/quality of evidence rating to establish how much confidence one could have in the estimates of effect. These are principally

<sup>7</sup> Higgins JPT, Green S, editors. Cochrane Handbook for Systematic Reviews of Interventions Version 5.1.0 [updated March 2011]: The Cochrane Collaboration; 2011.

single studies and the approach was to consider the outcomes per study in a rapid manner to establish some sense of GRADE 'lite' rating per outcome and then to derive an overall rating. The overall rating is based on the lowest rating from among the critical/important patient outcomes. The reporting in these studies was very poor, scarce, and the general methodologies were very weak. This has been a rapid, albeit sub-optimal application of GRADE methods, while seeking to apply as much rigor to a flawed body of evidence emerging from the current reporting across COVID-19 research in general<sup>8</sup>.

For any meta-analytical pooling if and when data allows, we plan to pool all peer-reviewed studies with non-peer-reviewed studies. We will present the combined analysis. However, we will also apply a sensitivity analysis and separate out peer-review studies to examine the estimates of effect based on the higher quality studies that would have undergone scientific scrutiny and will present these separately. There were some drug instances whereby we provide systematic-review (meta-analysis) evidence indirectly related to COVID-19 patients e.g. corticosteroids in patients with ARDS.

**Table 1:** All COVID-19 *in vitro* lab and *in vivo* (clinical) human studies published from January 2020

Author; study design; year	Treatment arm vs comparator; sample size; age (mean/median); male %	Patient co-morbidities; additional medications reported besides the intervention/control	Reported findings and author's stated conclusion  Note: methodological concerns	Risk of bias (RoB)*; GRADE certainty of evidence rating**
<b>Meplazumab (monoclonal antibody)</b>				
There is insufficient evidence to draw a conclusion on benefits and harms. The effectiveness is being evaluated in various randomized clinical trials.				
<b>OBSERVATIONAL (clinical)</b>				
Bian <sup>1</sup> ; observational treatment group with hospitalized concurrent control; 2020	Add-on 10 mg meplazumab (n=17 patients) vs hospitalized patients in the same period as controls (n=11); 28; mean 56.1; 53.5%	32% hypertension, 10.7% cardiovascular disease, 10.7% diabetes; lopinavir/ritonavir, recombinant human interferon $\alpha$ -2b, glucocorticoid, and antibiotics.	Meplazumab treatment significantly improved the discharge (p=0.006) and case severity (p=0.021) in the critical and severe patients vs control; the time to being virus negative in treatment was reduced relative to the control group (median 3, 95% CI (1.5–4.5) vs. 13, (6.5–19.5); p=0.014, HR=0.37, 95% CI (0.155–0.833)); suggested the need for further study in clinical trials as a potential therapeutic option in COVID-19.  Note: non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	High; Very low certainty <sup>1</sup>
<b>Ivermectin</b>				
There is insufficient evidence to draw a conclusion on benefits and harms. The effectiveness is being evaluated in various randomized clinical trials.				
<b><i>in vitro</i></b>				
Caly <sup>2</sup> ; observational; 2020	One group: a single addition to Vero-hSLAM cells 2 hours post infection with SARS-CoV-2 isolate Australia/VIC01/2020 at a MOI of 0.1, followed by the addition of 5 $\mu$ M ivermectin; NA	NA	Following a single addition to Vero-hSLAM cells 2 hours post infection, ivermectin at 24 hours contributed to a 93% reduction in viral RNA present in the supernatant of the samples treated with ivermectin compared to the vehicle DMSO. By 48 hours, there was an ~5000-fold reduction in viral RNA at 48 hours. Researchers concluded that ivermectin administration <i>in vitro</i> resulted in the effective loss of essentially all viral material by 48 hours, supporting further clinical study in COVID-19 patients.	High; Did not apply GRADE
<b>OBSERVATIONAL (clinical)</b>				
Patel <sup>24</sup> ; observational (registry-based); 2020	Ivermectin (150 mcg/Kg once following initiation of mechanical ventilation) vs SoC (no ivermectin); 1,970; not reported; not reported	Not reported	A survival benefit was reported for ivermectin (mortality rate 18.6% vs 7.7%; HR 0.18, 95% CI (0.07-0.48), log rank (Mantel-Cox) p<0.001; length of hospital stay 10.9 +/- 6.1 days vs 15.7 +/- 8.1 days and ICU stay was 6.0 +/- 3.9 days vs 8.2 +/- 6.2 days, both p<0.001.  Note: pre-print. non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	High; Very low certainty <sup>1</sup>
Patel <sup>11</sup> ; observational propensity-matched case-controlled (prospectively collected data);	Ivermectin (150mcg/Kg) administered once compared with COVID-19 patients receiving medical therapy without ivermectin; 1,408; mean 53.5; 55.1%	CAD 11.1%, diabetes 11.3%, COPD 2.8%, hypertension 24.8%, immune-compromised 2.8%; hydroxychloroquine,	In patients needing mechanical ventilation, a lesser number of patients died in the ivermectin group (7.3%) vs 21.3% control and the overall mortality rates were lower with ivermectin (1.4%) vs 8.5% with a corresponding HR 0.20, CI 95% 0.11-0.37, p<0.0001).  Note: apparent pre-print. non-randomized, potentially	Moderate-high; Very low certainty <sup>3</sup>

2020		azithromycin and corticosteroids	confounded, though propensity score matched on several variables and statistical adjustment, could not account for all unknown confounders, small events, judged as sub-optimal reporting of methods and outcomes.	
------	--	----------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

### Siltuximab (monoclonal antibody)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

#### OBSERVATIONAL (clinical)

<a href="#">Gritti</a> <sup>3</sup> ; observational (prospective cohort study); 2020	One group: patients received siltuximab at a median dose of 900 mg, ranging from 700 to 1,200 mg; received a second dose of siltuximab; 21; median 64.0 (IQR 48-75); 85.7%	43% had hypertension, 23.8% diabetes, 19% cardiovascular disease, 4.7% malignancies, 4.7% chronic kidney disease, and 4.7% cerebrovascular disease; no other medication reported but siltuximab	The results suggest a potential role of siltuximab in treating patients with ARDS secondary to SARS-CoV-2 infection.  Note: pre-print, non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	High; Very low certainty <sup>1</sup>
--------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------

### Danoprevir (antiviral)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

#### OBSERVATIONAL (clinical)

<a href="#">Chen</a> <sup>4</sup> ; observational; 2020	Treatment experienced (n=9) vs naïve patients (n=2), treatment naïve patients never received any antiviral therapies such as lopinavir/ritonavir and interferon nebulization before switching to danoprevir (all treated with danoprevir boosted by ritonavir in the presence or absence of interferon nebulization (the background therapy)); 11; median 44 (range 18-66); 36%	18% hypertension; not reported	After 4 to 12-day treatment with danoprevir boosted by ritonavir, all patients (n=11) discharged from the hospital based on normal body temperature for at least 3 days; there was substantial improvements in respiratory symptoms; the CT lung imaging revealed absorption and recovery of acute exudative lesions; there were 2 consecutive RT-PCR negative tests of SARS-CoV-2 nucleotide acid; researchers concluded that repurposing of danoprevir for COVID-19 should be considered within clinical trials.  Note: pre-print, non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	High; Very low certainty <sup>1</sup>
---------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------

### Tocilizumab/IL-6 (monoclonal antibody)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

#### OBSERVATIONAL (clinical)

<a href="#">Xu</a> <sup>5</sup> ; observational (retrospective cohort); 2020	All patients treated with tocilizumab; 21; mean 56.8 ± SD 16.5, ranged from 25 to 88 years; 85.7%	43% hypertension, 23.8% diabetes, 9.5% CHD, 4.8% COPD, 4.8% CKD, 4.8% bronchiectasis, 4.8% brain infarct, 4.8% auricular fibrillation; none reported	75.0% lowered oxygen intake and one patient required no oxygen therapy. CT scans showed lung lesion opacity was absorbed in 90.5%. The percentage of lymphocytes in peripheral blood returned to normal in 52.6% patients on the fifth day following treatment. Abnormally elevated C-reactive protein declined significantly in 84.2% of patients. No adverse reactions reported and 90.5% (n=19) discharged from hospital mean 13.5 days following the treatment with tocilizumab and the rest; 2 are undergoing good recovery; researchers concluded that tocilizumab should be considered within clinical trials for COVID-19.	High; Very low certainty <sup>1</sup>
------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------

			Note: pre-print, non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	
<a href="#">Cellina</a> <sup>34</sup> ; observational case-series (1 patient); 2020	2 doses of tocilizumab (8 mg/kg), 12 hours apart, on day 7 and 8; 1 patient; 64; male	None reported; none reported	Patient without significant clinical history presented with syncope with normal vitals; ear temperature was 38 °C, oxygen saturation 99% on room air, chest X-Rays showed mild linear densities in the lower and middle left lung fields, laboratory investigations showed increased white blood cell count (10.900 per $\mu$ L), elevated serum lactate level (250 U/L) and elevated reactive C protein (RCP) (89 mg/dL), other blood tests normal; COVID-19 detected in a throat swab sample by RT-PCR. Due to the worsening of the blood tests on the day 2, patient admitted; day 6, the patients developed dyspnea; decreased of oxygen saturation (90%) and further increase of CRP 336 mg/dL; white blood cell count was 10.800 per $\mu$ L; interleukin-6 was 80 ng/L; day 7, unenhanced chest CT showed the presence of diffused bilateral air space opacities, including ground glass opacities and consolidation; assisted ventilation started; patient administered 2 doses of tocilizumab (8 mg/kg), 12 hours apart, on day 7 and 8; day 9, CRP declined to 96 mg/dL and white blood cell count to 2.360 per $\mu$ L; patient clinical condition gradually improved and ventilatory support was gradually stopped; day 14, repeat chest CT revealed mark improvement (size reduction of air cells opacities, density reduction of consolidations, some ground glass opacities, peripheral reticular opacities, reduction of pleural effusion and mediastinal lymphadenopathy).	Not applied; Not applied
<a href="#">Roumier</a> <sup>44</sup> ; observational retrospective; 2020	Treated with IL-6 vs no IL-6 in matched controls group; 59 (n=30 IL-6 group and 29 in no IL-6 group); median age 50 years; 80%	Hypertension 30.5%, cardiovascular disease 14.7%, cerebrovascular disease 5%, chronic kidney disease 8.5%, HIV/AIDS 5%, immunosuppressive therapy 11.8%; 2 patients on IL-6 got azithromycin and 2 got methyl-prednisolone	Tocilizumab significantly reduced need for subsequent mechanical ventilation (weighted OR: 0.42; 95% CI [0.20-0.89]; p=0.025), unadjusted analysis showed a trend towards a reduction of mortality (OR: 0.25 95% CI [0.05-0.95], p=0.04), this significance faded with weighted analysis; in addition, based on only 23 patients (and 16 controls) treated outside of the ICU, tocilizumab significantly reduced the risk of subsequent ICU admission (weighted OR: 0.17; 95% CI [0.06-0.48]; p=0.001); as of April 4th 2020, based on the 30 patients treated with tocilizumab, 3 (10%) died, while 4/7 (57%) and 6/30 (20%) were discharged from the ICU and from hospital, respectively; tocilizumab was well-tolerated, there is mild hepatic cytolysis in n=2 and ventilator-acquired pneumonia in n=1.  Note: nonrandomized, confounded, optimal adjustments and steps not employed but the matching in the control group was an improvement (though not clear where the source of the control group was taken from e.g. was it drawn from the same population as treatment), small sample size, small events, and not optimally comparative. See reference 3 as these results differ from those of Gritti et al. who treated more severe patients requiring non-invasive ventilation with siltuximab (another IL-6R-targeted therapy).	High; Very low certainty <sup>1</sup>

## Favipiravir (antiviral)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

### RCT (clinical)

<a href="#">Chang</a> <sup>7</sup> ; RCT (open-label); 2020	120 assigned to favipiravir group (116 assessed, routine treatment + 1600 mg on the first day twice a day, 600 mg	27.9% hypertension, diabetes 11.4%, 95% COVID-19 pneumonia; none	Clinical recovery rate of day 7 between two groups, 61.2% favipiravir vs 5.7% arbidol (total patients), 71.4% vs 55.6% (moderate cases) respectively, 5.5% vs 0.0% (serious cases) respectively; patients with hypertension and/or diabetes 54.7%	High; Very low certainty <sup>1</sup>
-------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------	------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------

	from the second day to the end, twice a day) and 120 to arbidol group (120 assessed, 200 mg, 3 times a day to the end of the trial); 236; not reported clearly; 46.6%	reported	favipiravir vs 51.4% arbidol; adverse events 37/116 favipiravir vs 28/120 arbidol, note, 18 severe patients in the favipiravir group vs 9 severe patients in the arbidol group (imbalanced).  Note: pre-print, sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, and use of active comparator with unknown effectiveness for COVID-19.	
--	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

## OBSERVATIONAL (clinical)

<a href="#">Cai<sup>6</sup></a> ; observational (nonrandomized open-label); 2020	Oral FPV (Day 1: 1600 mg twice daily; days 2–14: 600 mg twice daily) plus interferon (IFN) $\alpha$ by aerosol inhalation in the FPV arm vs LPV/RTV (days 1–14: 400 mg/100 mg twice daily) plus IFN- $\alpha$ ; 80 (n=35 FPV and n 45=in LPV/RTV); median 47 (35.75–61); 43.8%	None reported; no additional medications reported, standard care included oxygen inhalation, oral or intravenous rehydration, electrolyte correction, antipyretics, analgesics, and antiemetic drugs.	Viral clearance median time for FPV (Group A), was estimated to be 4 days (IQR: 2.5–9) and significantly shorter than the time for patients in control group (Group B), which was 11 d (IQR: 8–13) (P < 0.001); for chest CT changes, on the 14 <sup>th</sup> day after treatment, the improvement rates of the chest CT in FPV significantly higher than those in the control arm (91.4% versus 62.2 %, 32/35 versus 28/45, p = 0.004). Adverse reactions in the FPV n=4 was four, significantly fewer than the 25 adverse reactions in the control arm (p < 0.001).  Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes, and active, retrospective comparator with unknown effectiveness for COVID-19.	High; Very low certainty <sup>1</sup>
----------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------

## Darunavir (antiviral)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

### *in vitro*

<a href="#">De Meyer<sup>8</sup></a> ; observational; 2020	Examined the <i>in vitro</i> antiviral activity of darunavir against a clinical isolate from a patient infected with SARS-CoV-2.	NA	Darunavir showed no activity against SARS-CoV-2 at clinically relevant concentrations (EC <sub>50</sub> >100 $\mu$ M). Remdesivir, used as a positive control, showed potent antiviral activity (EC <sub>50</sub> = 0.38 $\mu$ M).  Present findings do not support the use of darunavir for treatment of COVID-19.	Definitely high <sup>2</sup> (risk of bias assessed for <i>in vitro</i> studies using OHAT tool); Very low certainty <sup>1</sup>
------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------	----	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------

## Nelfinavir (antiviral)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

### *in vitro*

<a href="#">Yamamoto<sup>9</sup></a> ; observational; 2020	Assessed the 50% effective concentration (EC <sub>50</sub> ), the 50% cytotoxic concentration (CC <sub>50</sub> ), and the selectivity index (SI, CC <sub>50</sub> /EC <sub>50</sub> ); C <sub>max</sub> -EC <sub>50</sub> ratio (C <sub>max</sub> /EC <sub>50</sub> ) and C <sub>trough</sub> -EC <sub>50</sub> ratio (C <sub>trough</sub> /EC <sub>50</sub> ) were also calculated to evaluate the safety and efficacy of the 9 antivirals (plus lopinavir, ritonavir, saquinavir, atazanavir, tipranavir, amprenavir, darunavir, and indinavir).	NA	Nelfinavir effectively obstructs replication of SARS-CoV-2; the effective concentrations for 50% and 90% inhibition (EC <sub>50</sub> and EC <sub>90</sub> ) of nelfinavir was the lowest from among the 9 HIV-1 protease inhibitors.  Present <i>in vitro</i> findings are positive and support further clinical study of nelfinavir in COVID-19 patients. The methodology indicates a high risk of bias.	Definitely high <sup>2</sup> (risk of bias assessed for <i>in vitro</i> studies using OHAT tool); Very low certainty <sup>1</sup>
------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------

## Remdesivir (antiviral)

**There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.**

## OBSERVATIONAL (clinical)

<p><a href="#">Holshue</a><sup>10</sup>; case-series; 2020</p>	<p>1 COVID-19 patient (first in USA), aged 35 years, male, treated with remdesivir on compassionate use authorization</p>	<p>NA</p>	<p>Treatment with IV remdesivir began on the evening of day 7, and no adverse events were observed in association with the infusion. Vancomycin was discontinued on the evening of day 7, and cefepime was discontinued on the following day, after serial negative procalcitonin levels and negative nasal PCR testing for methicillin-resistant <i>Staphylococcus aureus</i>. On hospital day 8 (which was illness day 12), it was found that the patient's clinical condition improved significantly, whereby the supplemental oxygen was discontinued, and his oxygen saturation values improved to 94 to 96% while he was breathing ambient air. Bilateral lower-lobe rales were no longer present. Appetite improved, and the patient was asymptomatic aside from intermittent dry cough and rhinorrhea. All symptoms resolved.</p>	<p>Not applied; Not applied</p>
<p><a href="#">Grein</a><sup>11</sup>; case-series; 2020</p>	<p>Remdesivir; 53; median IQR 64 (48–71); 75</p>	<p>Hypertension 25%, diabetes 17%, hyperlipidemia 11%, asthma 11%; none reported</p>	<p>Researchers reported that at baseline, 30 patients (57%) were receiving mechanical ventilation and 4 (8%) were receiving ECMO. Based on a median follow-up of 18 days, 36 patients (68%) had an improvement in oxygen-support class, including 17 of 30 patients (57%) receiving mechanical ventilation who were extubated. A total of 25 patients (47%) were discharged, and 7 patients (13%) has died; mortality was 18% (6 of 34) among patients receiving invasive ventilation and 5% (1 of 19) among those not receiving invasive ventilation. Thirty-two patients incurred adverse events in follow-up. Small sample size, no control group, short duration follow-up.</p> <p>Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, and not optimally comparative.</p>	<p>High; Very low certainty<sup>1</sup></p>

## Chloroquine/hydroxychloroquine

**There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.  
Cardiovascular adverse events should be closely monitored**

(see GRADE Table and Figure in appendix)

## RCT (clinical)

<p><a href="#">Chen</a><sup>12</sup>; RCT; 2020</p>	<p>Hydroxychloroquine (HCQ) 400 mg per day for 5 days vs control (conventional treatment); 30 (15:15); 48.5 mean; 70%</p>	<p>None reported; nebulization with interferon alpha, and 80% patients in the experimental group received abidol vs 66.7% in control, 2 received lopinavir / ritonavir.</p>	<p>Nucleic acid of throat swabs was negative in 13 (86.7%) HCQ cases and 14 (93.3%) cases in the control group (<math>P&gt;0.05</math>), median duration from hospitalization to virus nucleic acid negative conservation was 4 (1-9) days in HCQ group, which is comparable to that in the control group [2 (1-4) days, median time for body temperature normalization in HCQ group was 1 (0-2) after hospitalization, which was also comparable to that in the control group 1(0-3), radiological progression was shown on CT images in 5 cases (33.3%) in the HCQ group and 7 cases (46.7%) in the control group. Researchers concluded that the standard dose of hydroxychloroquine sulfate does not show clinical effects in improving patient symptoms and accelerating virological suppression.</p> <p>Note: sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, and imbalanced co-treatment assignment.</p>	<p>High; Very low certainty<sup>1</sup></p> <p>See Figure 1, Table 1</p>
<p><a href="#">Chen</a><sup>13</sup>; RCT; 2020</p>	<p>5-day HCQ (n=31) (400 mg/d), control (n=31) received SoC; 62; 44.7 mean (SD 15.3); 46.8%</p>	<p>None reported; none reported</p>	<p>Body temperature recovery time and the cough remission time were significantly shortened in the HCQ treatment group (mean days and SD was 2.2 (0.4) in the HCQ groups vs 3.2 (1.3) in the control, <math>p=0.0008</math>. They also reported a greater proportion of patients with improved pneumonia (on chest CT)</p>	<p>High; Very low certainty<sup>1</sup></p>

			<p>in the HCQ treatment group (80.6%, 25 of 31) relative to the control group (54.8%, 17 of 31). Four patients in the control group developed severe illness (none in the treatment group) and there were 2 mild adverse events in the HCQ group.</p> <p>Note: the study group was generally younger, and the illness was mild on entry, suggestive that this was not an overly ill group to begin with and patients may have recovered on their own. No accounting of whether patients were taking any other medications prior to study entry or during the study; sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, and imbalanced co-treatment assignment.</p>	
<a href="#">Huang</a> <sup>14</sup> ; RCT; 2020	Twice-daily oral of 500 mg Chloroquine (n=10) versus 400/100mg Lopinavir/Ritonavir (n=12) for 10 days; 22; 44.0 mean (36.5 to 57.5); 59.1%	None reported; none reported	<p>Using RT-PCR, on day 13, all patients in the chloroquine group were negative, and 11 of 12 in the control group (lopinavir/ritonavir) were negative on day 14. Via lung CT on day 9, 6 patients in chloroquine group achieved lung clearance versus 3 in the comparison group. At day 14, the rate ratio based on CT imaging from the Chloroquine group was 2.21, 95% CI 0.81-6.62) relative to the control group. Five patients in the chloroquine group had adverse events versus no patients in the control group.</p> <p>Note: this small RCT appeared to show better effectiveness of chloroquine over lopinavir/ritonavir in moderate to severely ill COVID-19 patients; plagued with sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, and use of active comparator with uncertain treatment effectiveness against COVID-19.</p>	High; Very low certainty <sup>1</sup>
<a href="#">Silva Borba</a> <sup>15</sup> ; RCT; 2020	CQ (600mg CQ twice daily for 10 days or total dose 12g); or low dose CQ (450mg for 5 days, twice daily only on the first day, or total dose 2.7g); 81 (41 high doses vs 40 low dose); 51; 75	Hypertension 46.2%, diabetes 25.9%, alcoholism 26%, heart disease 9.2%, asthma 6.2%, CKD 7.5%, rheumatic disease 5.6%, liver disease 3.7%, TB 3.7%, HIV/AIDS 1.9%; corticosteroids 5.4%, ACE inhibitors 10.3%, oseltamivir 89.6%	<p>There were 11 deaths (13.5%) in high dose and low dose users; the high dose CQ arm presented more QTc&gt;500ms (25%), and a trend toward higher lethality (17%) than the lower dosage. Fatality rate was 13.5% (95%CI=6.9–23.0%), overlapping with the CI of historical data from similar patients not using CQ (95%CI=14.5-19.2%). In 14 patients with paired samples, respiratory secretion at day 4 was negative in only one patient; preliminary findings suggest that the higher CQ dosage (10-day regimen) should not be recommended for COVID-19 treatment because of its potential safety hazards.</p> <p>Note: sub-optimal randomization with randomization occurring before laboratory confirmation of SARS-CoV-2 infection, small sample size, small event number, and comparison of dose-comparison concurrent trial without a placebo control.</p>	Low-moderate; Moderate certainty <sup>3</sup>
<a href="#">Tang</a> <sup>16</sup> ; RCT; 2020	HCQ (a loading dose of 1, 200 mg daily for three days followed by a maintained dose of 800 mg daily for the remaining days) vs SoC; 150; mean 46.1±14.7; 54.7%	Diabetes 14.0%, hypertension 6%, others 31%; 80 patients used other drugs after randomization (not clearly reported)	<p>The overall 28-day negative conversion rate was not different between SOC plus HCQ and SOC group (85.4% versus 81.3%, p=0.34). Negative conversion rate at day 4, 7, 10, 14 or 21. A significant efficacy of HCQ on alleviating symptoms was observed (HR, 8.83, 95%CI, 1.09 to 71.3). There was a significantly greater reduction of CRP (6.98 in SOC plus HCQ versus 2.72 in SoC, milligram/liter, p=0.045) conferred by the addition of HCQ, which also led to more rapid recovery of lymphopenia, albeit no statistical significance. Adverse events found in 8.8% of SoC and 30% of HCQ recipients with two serious adverse events in the HCQ group.</p> <p>Note: sub-optimal randomization, allocation concealment, no blinding, small sample size, small event number, and comparison of dose-comparison concurrent trial without a placebo control.</p>	High; Low certainty <sup>1</sup>
<a href="#">Barbosa</a> <sup>28</sup> ; quasi-RCT; 2020	HCQ + supportive care vs supportive care alone; 63 (32	Not reported; not reported	HCQ administration was associated with worse outcomes.	High; Low certainty <sup>1</sup>

(submitted to NEJM for peer review, abstract form and available in the referenced blog)	HCQ vs 31 control);		Note: this paper was cited on a blog and appears to be a released paper submitted to NEJM; we felt the data is important as shed important light but we do not wish this reference or material to be cited out of regard to the originating authors; what we include we have taken from the blog as referenced ( <a href="https://blogs.sciencemag.org/pipeline/about-derek-low">https://blogs.sciencemag.org/pipeline/about-derek-low</a> )	
<b>OBSERVATIONAL (clinical)</b>				
<a href="#">Gautret<sup>17</sup></a> ; observational (open-label non-randomized trial); 2020	HCQ 600 mg daily 6 d n=26 (AZ added depending on clinical presentation); 42; 26 HCQ, 16 control; 45.1 ± 22.0 (mean/SD); 41.7%	None reported; none reported	<p>Researchers reported that 6 patients were asymptomatic, 22 had upper respiratory tract infection symptoms and eight had lower respiratory tract infection symptoms. Twenty cases were treated in this study and showed a significant reduction of the viral carriage at D 6-post inclusion compared to controls, and much lower average carrying duration than reported of untreated patients in the literature. Azithromycin (Z-Pak) added to hydroxychloroquine was significantly more efficient for virus elimination.</p> <p>Note: clinical follow-up and occurrence of side-effects were not discussed in the paper; non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, and sub-optimal reporting of methods and outcomes.</p>	High; Very low certainty <sup>1</sup>
<a href="#">Gautret<sup>18</sup></a> ; observational (uncontrolled non-comparative observational study); 2020	200 mg of HCQ three times per day for ten days combined with AZ (500 mg on D1 followed by 250 mg per day for the next four days); 80; 52.5 median, 52.5%	Cancer 6.3%, diabetes 11.2%, CAD 7.5%, hypertension 16.3%, chronic respiratory disease 10%, obesity 5%; immune-suppressive treatment 5%, non-steroid anti-inflammatory treatment 2.5%	<p>Nasopharyngeal viral load tested by qPCR and negative on day 8 was found in 93.7% of patients, not contagious (with a PCR Ct value&lt;34) at day 10 was found in 98.7%, negative virus cultures on day 5 was found in 98.7%, and length of stay in ICU (days) was a mean 4.6 days ± 2.1 SD (n=65). Researchers reported that patients were rapidly discharged from highly contagious wards with a mean length of stay of five days.</p> <p>Note: this study was judged to be at high risk of biased estimates due to it being a case-series observational study with no control group. Based on reporting, the cohort appears to be younger and the NEWS risk scoring system placed them all at very low risk of deteriorating, leaving one to speculate on if they would have recovered on their own. This group appears to be COVID-19 patients with mild illness. Patients may have recovered on their own; non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, and sub-optimal reporting of methods and outcomes.</p>	High; Very low certainty <sup>1</sup>
<a href="#">Molina<sup>19</sup></a> ; observational (narrative review); 2020	HCQ 600 mg/d for 10 days and AZ 500 mg Day 1 and 250 mg days 2 to 5; 11; 58.7 mean, 64%	None reported; none reported	<p>One patient, hydroxychloroquine and azithromycin were discontinued after 4 days because of a prolongation of the QT interval from 405 ms before treatment to 460 and 470 ms under the combination; They report that in the 10 living patients, repeated nasopharyngeal swabs were positive for COVID-19 RNA in 8 of the 10 patients (80%) at days 5 to 6 following treatment initiation. Researchers also questioned the one death and 3 ICU transfers<sup>14</sup> that suggest a worsening clinical outcome. They conclude that there is “no evidence of a strong antiviral activity or clinical benefit of the combination of hydroxychloroquine and azithromycin for the treatment of our hospitalized patients with severe COVID-19”.</p> <p>Note: this was a small consecutive series of patients followed to describe the response to the treatment, high risk of biased estimates; non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, and sub-</p>	High; Very low certainty <sup>1</sup>

<p><a href="#">Lancet</a><sup>20</sup>; network cohort and case-series; 2020</p>	<p>Network cohort and self-controlled case series study that involved 956,374 and 310,350 users of HCQ and sulfasalazine, and 323,122 and 351,956 users of HCQ-azithromycin and HCQ-amoxicillin.</p>	<p>ARDS 58%, COPD 5%, depression 14.5%, diabetes 13.2%, hyperlipidemia 30%, pneumonia 5.7%, renal impairment 4.2%, UTI 14.2%</p>	<p>optimal reporting of methods and outcomes.</p> <p>Data comprised 14 sources of claims data or electronic medical records from Germany, Japan, Netherlands, Spain, UK, and USA. Researchers found no excess risk of SAEs was when 30-day hydroxychloroquine and sulfasalazine use were compared. However, when azithromycin was added to hydroxychloroquine, researchers reported an increased risk of 30-day cardiovascular mortality HR 2.19 (95% CI 1.22-3.94), chest pain/angina HR 1.15 (95% CI 1.05-1.26), and heart failure HR 1.22 (95% CI 1.02-1.45)). The conclusion was that short-term hydroxychloroquine treatment was safe, but when azithromycin is added, it can induce heart failure and cardiovascular mortality, likely due to synergistic effects on QT length. Researchers urged caution in the use of this combination in COVID-19.</p> <p>Note: very confusing methods, non-randomized, confounded, not optimally comparative (e.g. comparison of hydroxychloroquine compared to hydroxychloroquine with azithromycin was not reported), sub-optimal reporting of methods and outcomes.</p>	<p>High; Very low certainty<sup>1</sup></p>
<p><a href="#">Chorin</a><sup>21</sup>; observational (retrospective cohort study); 2020</p>	<p>HQC plus azithromycin; 84; mean 63 ±15; 74%</p>	<p>CAD 11%, hypertension 65%, CKD 7%, diabetes 20%, COPD 8%, congestive heart failure 2%; Levofloxacin, Lopinavir/Ritonavir, or Tacrolimus 8%, Norepinephrine, Phenylephrine, or Vasopressin 13%, Amiodarone 7%</p>	<p>The QTc was prolonged maximally from baseline (days 3-4) and in 25 patients, the QTc increased more than 40ms. They also found that in 9 patients (11%), the QTc increased to &gt;500 ms, indicative of a high-risk group for malignant arrhythmia and sudden cardiac death.</p> <p>Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.</p>	<p>High; Very low certainty<sup>1</sup></p>
<p><a href="#">Mahévas</a><sup>22</sup>; observational (retrospective cohort study); 2020</p>	<p>HCQ at a daily dose of 600 mg in the first 48 hours after hospitalisation vs no HCQ; 181; median 60 years (IQR 52 to 68 years); 71.1%</p> <p>Note: in the HCQ group, 20% received concomitant azithromycin</p>	<p>Respiratory disease 11%, heart failure 3.3%, hypertension (cardiovascular illnesses) 51.9%, diabetes 8.3%, CKD 5%, immunodepression 11.6%; none reported</p>	<p>In terms of deaths or transfer to the ICU, 19% vs 21.6% occurred in the HCQ vs no HCQ groups respectively (RR 0.93 (0.48 to 1.81)), for day 7 mortality, 3.6% died in HCQ group vs 4.1% in the no-HCQ group (RR 0.61 (0.13 to 2.90)), occurrence of acute respiratory distress syndrome, 28.6% occurred in HCQ group vs 24.1% in no HCQ group (RR 1.15 (0.66 to 2.01)); in the 84 patients receiving HCQ within the first 48 hours, 8 (9.5%) experienced ECG modifications requiring HCQ discontinuation at a median of 4 days (3-9) after it began.</p> <p>Note: one of the stronger methodologies from among COVID-19 research releases; inverse probability of treatment weighting (IPTW) approach was used to closely approximate randomisation and try to balance the differences in baseline prognostic variables between treatment groups; some potentially important prognostic variables were not balanced in the modelling; overall, nonrandomized, confounded, optimal adjustments and steps such as masking not applied, small sample size, small events, and not optimally comparative.</p>	<p>Low-moderate; Very low certainty<sup>1</sup></p>
<p><a href="#">Magagnoli</a><sup>42</sup>; observational (retrospective analysis study); 2020</p>	<p>One of three cohorts based on medication exposure to hydroxychloroquine (HC) and azithromycin (AZ): 1) HC-treated (97); 2) HC- and AZ-treated (113); or 3) HC-untreated (158), all received standard support care; 368; median age (IQR) HC 70</p>	<p>Hyperlipidemia 15.7%, asthma 5.9%, 4.9%, congestive heart failure 20.4%, peripheral vascular disease 17.4%, cerebrovascular disease 12.8%, COPD 19.6%,</p>	<p>27 deaths (27.8%) HC group, 25 deaths (22.1%) HC+AZ group, 18 deaths (11.4%) no HC group, mechanical ventilation in 13.3% HC group, 6.9% HC+AZ group, and 14.1% no HC group (Table 4). Relative to the no HC group, there was higher risk of death from any cause in HC group (adjusted HR, 2.61; 95% CI, 1.10 to 6.17; p=0.03) but not in HC+AZ group (adjusted HR, 1.14; 95% CI, 0.56 to 2.32; P=0.72), no significant difference in the risk of ventilation in either the HC group (adjusted HR, 1.43; 95% CI, 0.53 to 3.79; p=0.48) or the</p>	<p>High; Very low certainty<sup>1</sup></p>

	(60-75), HC + AZ 68 (59-74), no HC 69 (59-75); 100%	diabetes 67.6%, renal disease 25%, cancer 16%, liver disease 1.1%; ACE inhibitor 13.9%, ARBs 8.9%	<p>HC+AZ group (adjusted HR, 0.43; 95% CI, 0.16 to 1.12; p=0.09), compared to the no HC group; no evidence that HCQ, with or without AZ, reduced the risk of mechanical ventilation and an association of increased overall mortality in HCQ alone.</p> <p>Note: adjusted for a large number of confounders including comorbidities, medications, clinical and laboratory abnormalities; however, even with propensity score adjustment for a large number of relevant confounders, one cannot discount the potential of selection bias or residual confounding; 100% male with median age was over 65 years, so not applicable directly to women or younger hospitalized populations; most were black; small sample size, small events number, though reporting was an improvement over COVID-19 reporting in general.</p>

### Corticosteroids

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

#### OBSERVATIONAL (clinical)

Lu <sup>23</sup> ; observational (retrospective cohort study); 2020	Corticosteroid (methylprednisolone, dexamethasone, and hydrocortisone) vs no drug; 61 (31:31); 57.5 mean; 52%	Hypertension 45%, diabetes 17.7%, CVD 6.5%, COPD 1.5%; oseltamivir, arbidol, lopinavir/ritonavir, ganciclovir, interferon- $\alpha$	<p>28-day mortality rate was 39% (12 out of 31) in case subjects and 16% (5 out of 31) in control subjects (P=0.09). Increased corticosteroids dosage was significantly associated with elevated mortality risk (P=0.003) in matched cases after adjustment for administration duration; every ten-milligram increase in hydrocortisone dosage was associated with additional 4% mortality risk (adjusted HR: 1.04, 95% CI: 1.01-1.07).</p> <p>Note: nonrandomized, confounded, optimal adjustments and steps such as masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.</p>	High; Very low certainty <sup>1</sup>
---------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------

#### SYSTEMATIC REVIEW/META-ANALYSIS (clinical evidence)

Mammen <sup>39</sup> ; meta-analysis; 2020	7 RCTs focusing on ARDS and not directly on the COVID-19 patient with ARDS; examining corticosteroids (hydrocortisone, methylprednisolone, dexamethasone, or inhaled budesonide) vs no-corticosteroids; n=851 patients; typically, > 50 years of age, hospitalized patients; typically >50 years	Not studied; not studied	<p>Three of seven trials (43%) enrolling 51.5% of the total sample had a low risk of bias. The loss to follow-up was rare: six trials (85.7%) had a near-complete follow-up with loss that was deemed not biasing, and with only one study, we judged had attrition greater than 5%; Corticosteroids reduced all-cause mortality (risk ratio [RR] 0.75, 95% CI: 0.59 to 0.95, p=0.02, moderate certainty) and duration of mechanical ventilation (mean difference [MD] -4.93 days, 95% CI: -7.81 days to -2.06 days, p&lt;0.001, low certainty), and increased ventilator-free days (VFD) (MD 4.28 days, 95% CI: 2.67 days to 5.88 days, p&lt;0.001, moderate certainty), when compared to placebo. Corticosteroids also increased the risk of hyperglycemia (RR 1.12%, 95% CI: 1.01 to 1.24, p=0.03, moderate certainty), and the effect on neuromuscular weakness was unclear (RR 1.30, 95% CI 0.80 to 2.11, p=0.28, low certainty).</p>	Low <sup>5</sup> ; i) mortality, moderate certainty ii) duration of mechanical ventilation, low certainty iii) increased ventilator-free days, moderate iv) risk of hyperglycemia, moderate v) neuromuscular weakness, low
--------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

### CONVALESCENT PLASMA (CP)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

#### OBSERVATIONAL (clinical)

Shen <sup>25</sup> ; case-series; 2020	Convalescent plasma (CP) to all; 5; age range 36-73 years; 60%	1 has hypertension and mitral insufficiency;	Following plasma transfusion, body temperature normalized within 3 days in 4 of 5 patients, the SOFA score decreased, and PAO2/FIO2 increased within 12 days (range, 172-276 before	High; Did not apply GRADE
----------------------------------------	----------------------------------------------------------------	----------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------

	Note: CP administered to all between 10 and 22 days after admission	antivirals (lopinavir/ritonavir; interferon alfa-1b; favipiravir; arbidol; darunavir) and corticosteroid methylprednisolone	and 284-366 after). Viral loads also decreased and became negative within 12 days after the transfusion, and SARS-CoV-2-specific ELISA and neutralizing antibody titers increased following the transfusion (range, 40-60 before and 80-320 on day 7). ARDS resolved in 4 patients at 12 days after transfusion, and 3 patients were weaned from mechanical ventilation within 2 weeks of treatment. Of the 5 patients, 3 have been discharged from the hospital (length of stay: 53, 51, and 55 days), and 2 are in stable condition at 37 days after transfusion.  Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	
<a href="#">Duan</a> <sup>26</sup> ; case-series; 2020	CP to all; 10; median age was 52.5 years (IQR, 45.0–59.5); 60%	Hypertension 30%, cardiovascular and cerebrovascular disease 10%; arbidol, ribavirin, remdesivir, Interferon- $\alpha$ , oseltamivir, peramivir and corticosteroid methylprednisolone	Following transfusion, the level of neutralizing antibody quickly increased to 1:640 in five cases, and maintained at a high level (1:640) in remaining of cases. Researchers reported that the clinical symptoms were substantially improved. They also found an increase in oxyhemoglobin saturation within 3 days. Several parameters tended to improve as compared to pre-transfusion. Improved parameters included “increased lymphocyte counts and decreased C-reactive protein. Radiological examinations showed varying degrees of absorption of lung lesions within 7 days. The viral load was undetectable after transfusion in seven patients who had previous viremia”. No severe adverse effects.  Note: pre-print, non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	High; Did not apply GRADE
<a href="#">Zhang</a> <sup>27</sup> ; case-series; 2020	CP to all; 4; 31, 55, 69, 73 years old and F, M, M, and pregnant F respectively	None reported; arbidol, lopinavir-ritonavir, ribavirin, interferon alpha inhalation, oseltamivir, albumin, zadaxin and immunoglobulin, antibacterial and antifungal drugs	Researchers reported no serious adverse reactions and all 4 patients recovered from COVID-19.  Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	High; Did not apply GRADE
<a href="#">Pci</a> <sup>29</sup> ; case-series; 2020	CP to all three; 3; not reported; not reported	Not reported; not reported	There were 2 patients with negative conversions and 1 failure due to anaphylaxis shock (discontinued); 1 <sup>st</sup> patient treated on 12 <sup>th</sup> day admission, turned severe, 2 <sup>nd</sup> treatment, then significantly improved (nucleic acid test became negative and symptoms improved) and met discharge criteria on 26 <sup>th</sup> day, 2 <sup>nd</sup> patient, treatment on 27 <sup>th</sup> day, the nucleic acid test became negative 4 days later, 3 <sup>rd</sup> patient was a 51-year old pregnant woman who suffered anaphylaxis shock and CP was discontinued).  Note: pre-print, small, only 3 patients, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes.	High; Did not apply GRADE
<a href="#">Shi</a> <sup>48</sup> ; case-series; 2020	1 patient, 50-year old female	Antiviral therapy plus interferon- $\alpha$ 2b, followed by lopinavir and ritonavir and empiric ceftriaxone	IVIg (20g) and thymalfasin were initiated, corticosteroid (intravenous 80 mg methylprednisolone) was also commenced and halved to 40mg two days later, symptoms deteriorated and ceftriaxone was replaced with piperacillin-tazobactam; initiated the administration of three consecutive sessions of PE with 600ml plasma (frozen plasma served as the sole replacement solution) followed by 20g IVIg from DOI 14 to DOI 17; symptoms were almost all rapidly relieved, with three	High; Did not apply GRADE

			consecutive sessions of PE treatment; no adverse events or complications were seen during PE treatment; oxygenation index increased with oxygen saturation of 96%; patient was breathing ambient air oxygen and the blood pressure was re-established.	
--	--	--	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

### Umifenovir/ arbidol (antiviral)

There is insufficient evidence to draw a conclusion on benefits and harms.  
The effectiveness is being evaluated in various randomized clinical trials.

#### RCT (clinical)

<a href="#">Li<sup>30</sup></a> ; RCT; 2020	Lopinavir/ritonavir (LPV/r) vs arbidol vs control; 44 (21, 16, 7 respectively); mean 49.4 years; 50%	Some type of underlying illnesses 34%; gamma globulin 11.3%, glucocorticoids 22.7%	The median time of positive-to-negative conversion of SARS-CoV-2 nucleic acid was 8.5 (IQR 3, 13) days in the LPV/r group, 7 (IQR 3, 10.5) days in the arbidol group and 4 (IQR 3, 10.5) days in the control group ( $p=0.751$ ). Researchers reported that there were no statistical differences between the three groups in the rates of antipyresis, cough alleviation, improvement of chest CT or the deterioration rate of clinical status (all $p > 0.05$ ). Five (23.8%) patients in the LPV/r group experienced adverse events during the follow-up period versus none in the other groups.  Note: pre-print, sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, imbalanced co-treatment assignment and use of active comparator with unknown effectiveness for COVID-19.	High; Low certainty <sup>1</sup>
<a href="#">Chen<sup>31</sup></a> ; RCT; 2020	Favipiravir versus Arbidol open-label RCT; 236 (116 favipiravir, 120 arbidol); unclear; 46.6%	Hypertension 27.9%, 11.4% diabetes; moxifloxacin hydrochloride tablets, cephalosporins, antiviral drugs other than the experimental drugs, glucocorticoid and human serum albumin.	There was no significant difference in clinical recovery rate at day 7, whereby 71 (61%) recovered in the favipiravir arm and 62 (52%) in the arbidol group. In patients with hypertension and/or diabetes, 23 (54.76) recovered in the favipiravir arm and 18 (51.43) in the arbidol arm (no significant difference). There were no deaths in either arm and 1 respiratory failure in the favipiravir arm and 4 (3.33) in the arbidol arm. Researchers reported 37 adverse events in the favipiravir arm and 28 in the arbidol arm. The reporting in this study was very poor and the methodology was weak. This was described as a randomized study but it was not. No proper description of randomization, allocation concealment, or masking was provided.  Note: pre-print, sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, imbalanced co-treatment assignment and use of active comparator with unknown effectiveness for COVID-19.	High; Very low certainty <sup>1</sup>

#### OBSERVATIONAL (clinical)

<a href="#">Deng<sup>32</sup></a> ; observational (retrospective cohort study); 2020	Arbidol combined with LPV/r (n=16) vs LPV/r alone (n=17); 33; mean 44.5; 51.5%	Median number of comorbidities was 0.7 (range 0–2); corticosteroid therapy; a number of antibacterial therapy agents; vasopressors.	Researchers reported that COVID-19 was not detected for 12 of 16 patients' nasopharyngeal specimens (75%) in the combination group after 7 days, relative to 6 of 17 (35%) in the monotherapy group ( $p < 0.05$ ). "After 14 days, 15 (94%) of 16 and 9 (52.9%) of 17, respectively, SARS-CoV-2 could not be detected ( $p < 0.05$ )". They reported that the chest CT scans were improving for 11 of 16 patients (69%) within the combination group following seven days relative to 5 of 17 (29%) in the monotherapy group ( $p < 0.05$ ).  Note: The sample was very small (n=33) and this was a nonrandomized retrospective design which is a weak design; overall, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes and use of active comparator with unknown effectiveness for COVID-19.	High; Very low certainty <sup>1</sup>
--------------------------------------------------------------------------------------	--------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------

<p><a href="#">Wang</a><sup>33</sup>; observational (retrospective case series); 2020</p>	<p>Arbidol vs no arbidol; 67; median 42.0(35.0-62.0); 46%</p>	<p>Hypertension 13%, cardiovascular disease 12%, diabetes 10%, COPD 6%, malignancy 6%, asthma 3%, chronic hepatitis 1%; antivirals, antibiotics, antifungals, corticosteroids</p>	<p>Mortality rate was 7.5%. Patients were divided into the SpO<sub>2</sub>≥90% group (n=55) and the SpO<sub>2</sub> &lt; 90% n=14; all deaths occurred in SpO<sub>2</sub> &lt; 90%, median age of the SpO<sub>2</sub> &lt;90% was 70.5, IQR 62-77, SpO<sub>2</sub> &lt;90% had more comorbidities (included the 5 that died) than SpO<sub>2</sub>≥90% group, 36% vs 7%, p=0.014, cardiovascular disease 36% vs 5%, p=0.07, diabetes 43% vs 2% p&lt;0.001. SpO<sub>2</sub> &lt; 90% group had more fever and dyspnea; no persons died who were treated with arbidol (n=36 patients), and all 5 deaths occurred in the group that received no arbidol (n=31 patients). The study showed that elderly persons (older) with underlying medical conditions were at increased risk of death.</p> <p>Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, and sub-optimal reporting of methods and outcomes.</p>	<p>High; Very low certainty<sup>1</sup></p>
<p><a href="#">Liu</a><sup>37</sup>; observational (retrospective cohort study); 2020</p>	<p>Arbidol vs no arbidol; 257; mean 59.1; 51.4%</p>	<p>52.1% pre-existing conditions; not clearly reported</p>	<p>Patients receiving arbidol had slightly higher SpO<sub>2</sub> level and smaller lesion area. Mortality was 7% among patients taking arbidol vs. 24.70% among patients who did not; adjustment for gender, pre-existing condition, log(age), log (SpO<sub>2</sub>), log (lesion size), log (admission data) and hospital, the OR was 0.169 (95% CI, 0.07 to 0.34) for arbidol; in terms of lesion size based on chest CT and adjusting for patients' characteristics and antiviral medication use, the ratio of the lesion size after the treatment vs before was 85.2% (95% CI, 74.4- 97.5; p=0.02) of that among patients not taking arbidol, indicative of much quicker lesion absorption. While the methods and analysis were very confusing and generally poor, it reported that arbidol is significantly related to a reduction in mortality among hospitalized COVID-19 patients; also reported was the combination of arbidol and oseltamivir being linked to a reduction in mortality, with no benefit with Lopinavir/Ritonavir.</p> <p>Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, sample not necessarily representative of clinical population, small events, not optimally comparative, and sub-optimal reporting of methods and outcomes.</p>	<p>High; Very low certainty<sup>1</sup></p>

## Lopinavir/ritonavir (LPV/r) protease inhibitor

There is insufficient evidence to draw a conclusion on benefits and harms. The effectiveness is being evaluated in various randomized clinical trials.

### RCT (clinical)

<p><a href="#">Li</a><sup>30</sup>; RCT; 2020</p>	<p>Lopinavir/ritonavir (LPV/r) vs arbidol vs control; 44 (21, 16, 7 respectively); mean 49.4 years; 50%</p>	<p>Some type of underlying illnesses 34%; gamma globulin 11.3%, glucocorticoids 22.7%</p>	<p>The median time of positive-to-negative conversion of SARS-CoV-2 nucleic acid was 8.5 (IQR 3, 13) days in the LPV/r group, 7 (IQR 3, 10.5) days in the arbidol group and 4 (IQR 3, 10.5) days in the control group (p=0.751). Researchers reported that there were no statistical differences between the three groups in the rates of antipyresis, cough alleviation, improvement of chest CT or the deterioration rate of clinical status (all p &gt; 0.05). Five (23.8%) patients in the LPV/r group experienced adverse events during the follow-up period versus none in the other groups.</p> <p>Note: pre-print, sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, imbalanced co-treatment assignment and use of active comparator with unknown effectiveness for COVID-19.</p>	<p>High; Low certainty<sup>1</sup></p>
<p><a href="#">Huang</a><sup>14</sup>; RCT;</p>	<p>Twice-daily oral of 500 mg</p>	<p>None reported; none</p>	<p>Using RT-PCR, on day 13, all patients in the chloroquine group</p>	<p>High;</p>

2020	Chloroquine (n=10) versus 400/100mg Lopinavir/Ritonavir (n=12) for 10 days; 22; 44.0 mean (36.5 to 57.5); 59.1%	reported	were negative, and 11 of 12 in the control group (lopinavir/ritonavir) were negative on day 14. Via lung CT on day 9, 6 patients in chloroquine group achieved lung clearance versus 3 in the comparison group. At day 14, the rate ratio based on CT imaging from the Chloroquine group was 2.21, 95% CI 0.81-6.62) relative to the control group. Five patients in the chloroquine group had adverse events versus no patients in the control group.  Note: this small RCT appeared to show better effectiveness of chloroquine over lopinavir/ritonavir in moderate to severely ill COVID-19 patients; overall, sub-optimal randomization, allocation concealment, blinding, small sample size, small event number, and use of active comparator with uncertain treatment effectiveness against COVID-19.	Very low certainty <sup>1</sup>
<a href="#">Cao</a> <sup>36</sup> ; RCT; 2020	LPV/r (400 mg and 100 mg, respectively) twice a day for 14 days, in addition to standard care vs standard care alone; 100 (99 intervention 100 control); median 58 years IQR 49 to 68 years; 60.3%	Diabetes 11.6%, cerebrovascular 6.5%, cancer 3%; interferon on enrollment 11.1%, vasopressors 22.1%, glucocorticoid 33.7%, antibiotic 95%	Time to clinical improvement — median no. of days (IQR) 16.0 (13.0 to 17.0) vs 16.0 (15.0 to 18.0); Day 28 mortality — no. (%) n=19 (19.2) vs 25 (25.0) intervention vs control respectively; Clinical improvement — no. (%) day 28 n=78 (78.8) vs 70 (70.0); ICU length of stay — median no. of days (IQR) 6 (2 to 11) vs 11 (7 to 17); Hospital stay — median no. of days (IQR) 14 (12 to 17) vs 16 (13 to 18) The median interval time between symptom onset and randomization was 13 days (IQR, 11 to 16 days).  Note: open-label, no blinding, imbalanced viral loads between groups with higher baseline viral loads in the LPV/r group, small sample size, and small event number.	High; Low certainty <sup>4</sup>
<b>OBSERVATIONAL (clinical)</b>				
<a href="#">Ye</a> <sup>35</sup> ; observational; 2020	LPV/r vs plus adjuvant drugs only no LPV/r (adjuvant drugs only); 47 (42 treatment vs 5 control); aged between 5 and 68, of which 9 were under 30 and 38 were over 30; 42%	Hypertension 17%, diabetes 17%; arbidol, moxifloxacin	Improvement in body temperature for both groups admission to the 10th day treatment; body temperature of intervention group declined faster than control, some reductions in proportions of white blood cells, lymphocytes and C-reactive protein in intervention vs control, proportion with abnormal alanine aminotransferase and aspartate aminotransferase in intervention lower than control; reduced number of days testing negative in intervention group.  Note: Non-randomized, confounded, optimal adjustments and steps such as stratification and masking not applied, sample not necessarily representative of clinical population, small events, not optimally comparative, and sub-optimal reporting of methods and outcomes.	High; Very low certainty <sup>1</sup>
<a href="#">Deng</a> <sup>32</sup> ; observational (retrospective cohort study); 2020	Arbidol combined with LPV/r (n=16) vs LPV/r alone (n=17); 33; mean 44.5; 51.5%	Median number of comorbidities was 0.7 (range 0-2); corticosteroid therapy; a number of antibacterial therapy agents; vasopressors.	COVID-19 was not detected for 12 of 16 patients' nasopharyngeal specimens (75%) in the combination group arbidol plus LPV/r following 7 days, relative to 6 of 17 (35%) in the monotherapy group (p < 0.05). "After 14 days, 15 (94%) of 16 and 9 (52.9%) of 17, respectively, SARS-CoV-2 could not be detected (p < 0.05)". They reported that the chest CT scans were improving for 11 of 16 patients (69%) within the combination group following seven days relative to 5 of 17 (29%) in the monotherapy group (p < 0.05). The sample was very small (n=33) and this was a nonrandomized retrospective design which is a weak design.  Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, not optimally comparative, sub-optimal reporting of methods and outcomes and use of active comparator with unknown effectiveness for COVID-19.	High; Very low certainty <sup>1</sup>

## Interferon-alpha $\alpha$

**There is no quality evidence to support a recommendation on its therapeutic use**  
**The effectiveness is being evaluated in randomized clinical trials.**

**OBSERVATIONAL (clinical)**

<a href="#">Meng</a> <sup>38</sup> ; observational; 2020	Medical personnel, low-risk group received rhIFN- $\alpha$ nasal drops for 28 days (n=2,415) vs the high-risk group who received rhIFN- $\alpha$ nasal drops combined with thymosin- $\alpha$ 1, once a week (n=529); 2,944; 34.6; 30%	Not reported; not reported	<p>There were no new cases of COVID-19 pneumonia during follow-up in low-risk group, and no new cases were found in the high-risk group. Adverse effects among a few personnel included transient irritation which resolved soon after it began. Researchers suggest that in low and high-risk level hospital personnel, with the proper protective equipment (first and second-level) and at low risk to begin, when given IFN-<math>\alpha</math> nasal drops with or without thymosin alpha, are effectively prevented from developing COVID-19 disease. The data on testing prior to the study and post study ending is not available which raises many questions about this study.</p> <p>Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small events, not optimally comparative, and sub-optimal reporting of methods and outcomes. In addition, the use thymosin-<math>\alpha</math>, an agent with unknown effectiveness for COVID-19 obscures the treatment effect.</p>	High; Very low certainty <sup>1</sup>
----------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------

## Interferon-beta $\beta$

**There is no quality evidence to support a recommendation on its therapeutic use**  
**The effectiveness is being evaluated in various randomized clinical trials.**

**SYSTEMATIC REVIEW/META-ANALYSIS (clinical evidence)**

<a href="#">Mammen</a> <sup>40</sup> ; meta-analysis; 2020	2 RCTs focusing on ARDS and not directly on the COVID-19 patient with ARDS; examining interferon-beta vs no interferon-beta; n=392 patients; not reported; not reported	Not studied, not studied	Use of IFN $\beta$ had no significant difference on 28-day hospital mortality (risk ratio [RR] 0.59, 95% CI: 0.13 to 2.67, p=0.49, or on ventilator-free days (VFD) (MD 4.85 days, 95% CI: -3.25 days to 12.93 days, p=0.24), compared to no IFN $\beta$ . IFN $\beta$ also had no significant impact on the risk of adverse events (RR 0.98%, 95% CI: 0.94 to 1.03, p=0.47). The use of IFN $\beta$ does not appear to improve mortality, VFD or adverse events in ARDS patients; based on two small studies with limited numbers of events, which raises uncertainties in IFN $\beta$ true effects. The analysis of one study reveals increased mortality with the concomitant use of corticosteroids and IFN $\beta$ , suggesting careful consideration of drug-drug interactions with this combination.	Low <sup>5</sup> ; i) mortality 28-day, very low certainty ii) ventilator-free days, very low certainty iii) adverse events, low certainty
------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------

## Heparin

**There are specific recommendations on the use of antithrombotic agents.**<sup>46 47</sup>

Studies are ongoing to evaluate the preventive and therapeutic use of antithrombotic agents to mitigate the thrombotic and hemorrhagic events and assess the potential drug interactions with investigational drugs.

**OBSERVATIONAL (clinical)**

<a href="#">Negri</a> <sup>43</sup> ; observational, case-series; 2020	enoxaparin 1 mg/kg SC every 24 hours (OD). Patients with a creatinine clearance under 30 mL/min received subcutaneous unfractionated heparin at a dose of 5,000 units every 8 or 6 hours; 27; mean 56 $\pm$ 17; 70%	n=15 patients had diabetes 11%, hypertension 26%, heart disease 11%, previous lung disease 7%, cancer 4%, other 26%; 10-day course of azithromycin (500mg on day 1, then 250mg daily), methylprednisolone 40mg daily if a	<p>15 (56%) discharged after an average 7.3 (<math>\pm</math> 4.0) days, 1 discharged and lost follow-up, 9 patients (33%) admitted to ICU, 3 (33%) then discharged to the ward after an average 9.3 (<math>\pm</math>4.5) days, 8 (30%) required intubation, half of which (4 patients) successfully extubated after an average 10.3 (<math>\pm</math> 1.5) days of mechanical ventilation and other half (4 patients) currently being weaned off the ventilator, 2 required a tracheostomy; no deaths or haemorrhagic complications due to heparin anticoagulation.</p> <p>Note: nonrandomized, confounded, optimal adjustments and steps such as stratification and masking not applied, small sample size, small events, and not optimally comparative.</p>	High; Very low certainty <sup>1</sup>

### α-Lipoic acid

There is no quality evidence to support a recommendation on its therapeutic use  
The effectiveness is being evaluated in various randomized clinical trials.

<b>RCT (clinical)</b>				
Zhong <sup>44</sup> ; RCT, single-blind; 2020	α-Lipoic acid (ALA) n=8 1200 mg/d, intravenous infusion) once daily plus for 7 days plus standard care vs placebo n=9 saline infusion plus standard care for 7 days; median (IQR) 63 (59-66); 76.5%	Hypertension 47%, diabetes 23.5%, coronary heart disease 5.9%; none reported	Researchers found no significant difference in SOFA score between the placebo group and the ALA group (p=0.36); the 30-day all-cause mortality was 77.8% (7/9) in the placebo group, and 37.5% (3/8) in the ALA group (p=0.09).  Note: single-blind (participants and study personnel were aware of the study-group assignments), very small number of patients, very small events, randomization, allocation concealment not optimal or clear.	High; Very low <sup>6</sup>

#### Notes and considerations:

\*ratings are high vs moderate-low vs low RoB; note, high risk for RCTs would be for serious flaws in randomization, allocation concealment, blinding, severe data loss, baseline imbalances etc. and for observational non-randomized studies (single or two-arm), there could be no adjustment for confounders, no masking, stratification etc.

\*\*ratings are high, moderate, low, very low certainty (GRADE); note using GRADE, RCTs start as high certainty/quality evidence, observational studies start as low certainty/quality; for imprecision, the focus is on sample size, number of reported events, width of confidence intervals (if reported); note also that the use of GRADE in this application for RCTs and observational studies focuses mainly on risk of bias and imprecision given we are dealing with single studies and domains of consistency (heterogeneity), indirectness, and publication bias are not ideally applicable. We would consider the magnitude of effect, dose-response, and plausible residual confounding for observational designs.

<sup>1</sup>risk of bias and imprecision (small sample sizes, small event numbers), downgrade one level each (one may argue that since observational studies start as low certainty that the risk of bias due to lack of randomization etc. is already accounted for and no need to downgrade for risk of bias; in any case, one downgrade for imprecision still leads to very low; in some sense in the use of the ROBINS-I tool for risk of bias in nonrandomized studies that is suggested to start at high certainty, will become low due to the challenges of nonrandomization etc.).

<sup>2</sup>risk of bias for in vitro studies uses OHAT risk of bias tool/NTP

url: Handbook for Conducting a Literature-Based Health Assessment Using OHAT Approach for Systematic Review and Evidence Integration. Available online: [http://ntp.niehs.nih.gov/ntp/ohat/pubs/handbookjan2015\\_508.pdf](http://ntp.niehs.nih.gov/ntp/ohat/pubs/handbookjan2015_508.pdf) whereby questions such as i) was administered dose or exposure level adequately randomized ii) was allocation to study groups adequately concealed and iii) can we be confident in the exposure characterization, were answered. Rating are definitely high, probably high, probably low, definitely low.

<sup>3</sup>imprecision downgrade one level due to small sample size and/or events.

<sup>4</sup>risk of bias downgrade due to open-label and imprecision due to small sample size and events; down-grade of two levels

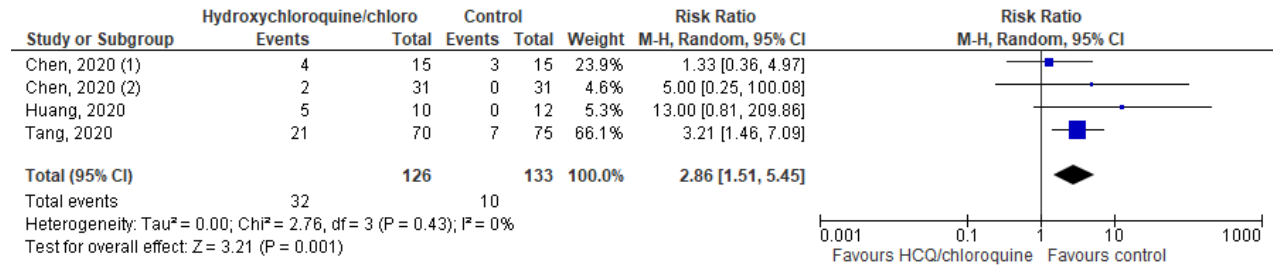

<sup>5</sup>Low risk of bias based on application of AMSTAR II tool (url: [https://amstar.ca/Amstar\\_Checklist.php](https://amstar.ca/Amstar_Checklist.php)).

<sup>6</sup>Very low RCT due to single downgrade risk of bias and double for imprecision

## Appendix

### Hydroxychloroquine /chloroquine

**Figure 1:** Adverse events combined in use of HCQ / CQ (pre-publications, non-peer review)

**Table 1:** GRADE certainty hydroxychloroquine/chloroquine adverse events (all combined)

Certainty assessment							No of patients		Effect		Certainty	Importance
No of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	hydroxychloroquine /chloroquine	no HCQ/CQ or control	Relative (95% CI)	Absolute (95% CI)		
<b>Adverse outcomes (all combined)</b>												
4	randomised trials	serious <sup>a</sup>	not serious	not serious	serious <sup>b</sup>	none	32/126 (25.4%)	10/133 (7.5%)	<b>RR 2.86</b> (1.51 to 5.45)	<b>140 more per 1,000</b> (from 38 more to 335 more)	⊕⊕○○ LOW	CRITICAL

**CI:** Confidence interval; **RR:** Risk ratio

#### Explanations

a. unclear/absent randomization, concealment, blinding, sub-optimal outcomes, imbalanced co-treatment assignment

b. small sample size, small number of events (OIS not met)
