ABSTRACT

A rapid systematic review was carried out to evaluate the current evidence related to the presence of SARS-CoV-2 in breast milk from pregnant women with COVID-19. Eight studies analyzing the presence of SARS-CoV-2 RNA in the breast milk of 24 pregnant women with COVID-19 during the third trimester of pregnancy were found. All patients had fever and/or symptoms of acute respiratory illness and chest computed tomography images indicative of COVID-19 pneumonia. Most pregnant women had cesarean delivery (91.7%) and two neonates had low birthweight (< 2 500 g). Biological samples collected immediately after birth from upper respiratory tract (throat or nasopharyngeal) of neonates and placental tissues showed negative results for the presence SARS-CoV-2 by RT-PCR test. No breast milk samples were positive for SARS-CoV-2 and, to date, there is no evidence on the presence of SARS-CoV-2 in breast milk of pregnant women with COVID-19. However, data are still limited and breastfeeding of women with COVID-19 remains a controversial issue. There are no restrictions on the use of milk from a human breast milk bank.

Keywords

Coronavirus infection; virus diseases; pneumonia, viral; pandemics; SARS virus; breast feeding.

SARS-CoV-2 is a novel emerged positive-strand RNA virus associated with an acute respiratory distress disease known as COVID-19. Studies have suggested that transmission of SARS-CoV-2 is primarily from person to person through respiratory droplets (1,2). In addition, there is emergent evidence that the virus could be detected in biological fluids including bronchoalveolar lavage fluid specimens (3), blood (3,4) and saliva (5), but substantial knowledge gaps remain regarding the presence of SARS-CoV-2 in the breast milk. Recently, a report in *Science* discussed the wrenching choices of pregnant women with COVID-19 after childbirth including whether or not they should breastfeed their children (6).

METHODS

We performed a rapid systematic review to evaluate the current evidence related to the presence of SARS-CoV-2 in breast milk from pregnant women with COVID-19. The study was conducted in accordance with the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines (7), but given emergency-need for this review, PROSPERO registration was not sought. Using terms related to coronavirus, we searched in PubMed, Web of Science, Scopus, China National Knowledge Infrastructure database, and grey literature (Google Scholar and preprint repositories) to identify studies reporting results of RT-PCR tests on breast milk in pregnant women with

laboratory-confirmed SARS-CoV-2 infection. Searches were performed up to March 30, 2020 and updated on April 21, 2020.

RESULTS AND DISCUSSION

We found eight studies (8–15) analyzing the presence of SARS-CoV-2 RNA in the breast milk of 24 pregnant women with COVID-19 during the third trimester of pregnancy (Table 1). All patients had fever and/or symptoms of acute respiratory illness and chest computed tomography (CT) images indicative of COVID-19 pneumonia. Most pregnant women had cesarean delivery (91.7%) and two neonates had low birthweight (< 2,500 g). Biological samples collected immediately after birth from upper respiratory tract (throat or nasopharyngeal) of neonates and placental tissues showed negative results for the presence SARS-CoV-2 by RT-PCR test. In addition, no breast milk samples were positive for SARS-CoV-2. In three studies (10,12,13) there was a clear recommendation for mother's to not breastfeed their children despite the lack of evidence on the potential viral transmission via breast milk.

As the coronavirus pandemic takes hold, pregnant women infected with SARS-CoV-2 experience fear and uncertainties regarding the care of their child. Making decisions without a robust evidence base may influence mother-child interactions and lead to poor outcomes. Furthermore, there is a lack of consensus among health agencies regarding breastfeeding for women with COVID-19. In February 2020, the National Health Commission of China recommended that neonates of pregnant women with suspected or confirmed COVID-19 should be isolated in a designated unit for at least 14 days and should not be breastfed due to the high risk of infection (16). Although this expert working group has suggested breastfeeding only in cases of negative tests for SARS-CoV-2, this warning may contribute to reducing breastfeeding by women with no exposure to the virus which may lead to infant poor health outcomes. On the other hand, interim guidance provided by the Centers

for Disease Control and Prevention (CDC) (17) and the World Health Organization (WHO) (18) advises that breastfeeding should be determined by the mother in coordination with her family and healthcare providers, and all possible prevention measures to avoid spreading the virus to the infant must be taken including wearing a mask and washing hands and breasts with soap and water before breastfeeding. If the woman opts to express breast milk, all recommendations for cleaning the breast pumps and utensils after each use must be rigorously followed. Consideration should be given to the possibility of someone healthy providing breast milk to the infant using a cup or spoon. This person must receive training from a qualified professional before starting procedures. If there is no production of breast milk by the mother, a human milk bank should be contacted. There are no restrictions on the use of milk from a human breast milk bank (19,20). The possibility of drug excretion into breast milk with potential adverse effects in breastfed neonates should also be analyzed (21). To date, there is no evidence on the presence of SARS-CoV-2 in breast milk of pregnant women with COVID-19. Data provided on current literature are still limited and breastfeeding of women with COVID-19 remains a controversial issue. Further studies with large samples are needed to confirm these results particularly given the importance of breastfeeding in preventing other childhood illnesses.

Lactancia materna en mujeres con COVID-19: falta de evidencia sobre la presencia de SARS-CoV-2 en la leche materna

RESUMEN

Se llevó a cabo una revisión sistemática rápida para evaluar la evidencia disponible sobre la presencia de SARS-CoV-2 en la leche materna de mujeres embarazadas afectadas con COVID-19. Se encontraron ocho estudios que analizaron la presencia de ARN de SARS-CoV-2 en la leche materna de 24 mujeres embarazadas con COVID-19 durante el tercer trimestre del embarazo. Todas las pacientes tenían fiebre o síntomas de enfermedad respiratoria aguda e imágenes de tomografía computarizada de tórax indicativas de neumonía por COVID-19. La mayoría de las mujeres embarazadas (91,7%) tuvieron un parto por cesárea y dos neonatos presentaron bajo peso al nacer (< 2 500 g). Las muestras biológicas recogidas inmediatamente después del parto de las vías respiratorias superiores (faringe o nasofaringe) de los neonatos y los tejidos placentarios mostraron resultados negativos para SARS-CoV-2 mediante RT-PCR. Ninguna muestra de leche materna fue positiva para SARS-CoV-2 y, hasta la fecha, no hay evidencia de la presencia de SARS-CoV-2 en la leche materna de las mujeres embarazadas con COVID-19. Sin embargo, los datos disponibles todavía son limitados y la lactancia materna en las mujeres con COVID-19 sigue siendo un tema controvertido. No hay restricciones para el uso de leche materna de banco.

Aleitamento materno em mulheres com COVID-19: falta de evidência da presença da SARS-CoV-2 no leite materno

RESUMO

Foi realizada uma revisão sistemática rápida para avaliar as evidências atuais relacionadas à presença da SARS-CoV-2 no leite materno de mulheres grávidas com COVID-19. Foram encontrados oito estudos analisando a presença de RNA do SARS-CoV-2 no leite materno de 24 gestantes com COVID-19 durante o terceiro trimestre de gravidez. Todas as pacientes apresentavam febre ou sintomas de doença respiratória aguda e imagens de tomografia computadorizada do tórax indicativas de pneumonia pela COVID-19. A maioria das gestantes teve parto cesáreo (91,7%) e dois recém-nascidos tiveram baixo peso ao nascer (< 2 500 g). As amostras biológicas coletadas imediatamente após o nascimento do trato respiratório superior (faringe ou nasofaringe) de neonatos e tecidos placentários apresentaram resultados negativos para a presença do SARS-CoV-2 pelo teste RT-PCR. Nenhuma amostra de leite materno foi positiva para o SARS-CoV-2 e, até à data, não há evidências da presença do SARS-CoV-2 no leite materno de mulheres grávidas com COVID-19. No entanto, os dados ainda são limitados e a amamentação de mulheres com COVID-19 continua a ser uma questão controversa. Não há restrições ao uso de leite de um banco de leite materno humano.
