FOREWORD

As is illustrated by the present series of reports there has been a steady improvement in the Region of local and national reporting systems for the notifiable diseases.

A special impetus to this development has been given by the increasing number of programs for the eradication of certain major communicable diseases such as malaria and smallpox. For the ultimate success of these programs complete and reliable information about the occurrence of the disease concerned is of critical importance. Such information is a prerequisite for effective action at the local and national levels and for coordination of the programs at the regional level.

This report of notifiable diseases in the Americas for 1963 is the third annual publication in this series. Efforts have been made to release the data provided by the health services as promptly as possible and it is hoped that this will increase their value to health officials.

I wish to express my appreciation for the continued cooperation of the Ministries of Health in the provision of the basic data for these reports.

Abraham Horwitz
Director

INTRODUCTION

Many of the communicable diseases occurring in the Americas are common to large parts of the continent and international collaboration is playing an increasing part in the developing of programs for their control or eradication. Considerable importance is therefore attached to the steadily progressing exchange between the countries of the Americas of information on the distribution and characteristics of communicable diseases. The present procedures for the international reporting of such diseases are based on the provisions of the *International Sanitary Regulations* (1) and the *Pan American Sanitary Code*. (2) A detailed description of the reporting procedures is included in a *Guide for the Reporting of Statistical Information in the Health Field*. (3)

This report for the year 1963 is the sixth in a series of publications on reported cases of notifiable diseases in the Americas. The first three publications contained data for the years 1946-1955, 1949-1958 and 1959-1960. (4) Beginning with the year 1961 the publications have been prepared annually (5) in order to provide the health workers concerned with more current information.

The present report is based mainly on final summary data for 1963 provided by health authorities of the countries in response to a joint annual questionnaire from the Pan American Health Organization and

Headquarters of the World Health Organization. Provisional returns received through monthly reporting procedures have been used in a few instances in which it was not possible to obtain final data for 1963.

The data received by the Pan American Health Organization are derived from the national systems for reporting of communicable diseases. These systems differ in the diseases included and in the degree of completeness of reporting. The quarantinable diseases, viz. cholera, plague, louse-borne relapsing fever, smallpox, louse-borne typhus and yellow fever are notifiable in all countries by international agreement. In addition a number of other communicable diseases are declared notifiable by national laws or regulations. The list of such notifiable diseases varies among countries.

Data on deaths may contribute materially to an understanding of the epidemiology of many communicable diseases. Beginning with the report for 1961 data derived from national death registration systems have therefore been included whenever available.

The Veterinary Services of the Ministries of Health or of Agriculture have contributed to the information on cases and other indices of zoonoses in animals.

ORGANIZATION OF REPORT

The available data for each country and territory in the Region of the Americas are presented in seven main tables (I-VII). In Tables I and II are shown the total numbers of reported cases of notifiable diseases with rates per 100,000 population. For comparison the corresponding numbers of cases reported for 1962 and the medians for the five-year period 1958-1962 are given. When data are not available for every year of this period, medians are based on fewer years in the period, that is, either four or three years.

In Table III, distributions of reported cases by month of occurrence are shown for selected diseases. The age distributions of reported cases of some diseases appear in Table IV. The occurrence of the quarantinable diseases and of leprosy, malaria and yaws is presented by major political divisions of each country in Table V. Table VI includes data on cases of zoonoses in man and animals. Numbers of registered deaths from notifiable diseases in 1963 are given in Table VII.

Two appendix tables provide population figures for 1963. Estimated midyear populations for all countries and territories of the Americas are shown in Appendix

Table A; these estimates are based on published figures of the United Nations. Table B gives estimated populations of reporting areas in six countries, as provided by the national health authorities.

A short analysis of the occurrence of selected diseases in the Region is given in the Introduction. This analysis is illustrated by Summary Tables 1-8 and Figures 1-9. In one section of the analysis data are presented for purposes of comparison for three regions of the Americas, Northern, Middle and South. Northern America includes Canada, the United States, Bermuda and St. Pierre and Miquelon. Middle America comprises Mexico, Central America, Panama and the Caribbean Islands. The countries and territories of South America and the Falkland Islands make up the third region. This division into three regions is in accordance with that used by the United Nations, except that Greenland being a part of the European Region of WHO is excluded.

In each part of the report the diseases are arranged in alphabetical order. In the seven main tables the category number of the *International Classification of Diseases* is given in parenthesis after the name of each disease.

COMPLETENESS OF REPORTING

Data on reported cases of notifiable diseases may be affected by a number of factors and these must be considered in any evaluation. Incomplete reporting is one such factor. Completeness of reporting varies markedly both among and within countries depending among other things on the adequacy of local and national reporting procedures, the availability of medical attention and the stress and value placed on reporting of individual diseases. Underreporting tends to be substantial where medical personnel and

facilities are relatively scarce and travel and communication difficult as is the case in many rural areas in the Americas.

The operation of special programs or campaigns for the control or eradication may initially lead to a substantial increase in the number of cases reported. In the interpretation of the time trend of many diseases, for instance malaria, this possibility must be kept in mind. The time trend may reflect not only changes in incidence

of a disease but also changes in the completeness with which cases are recognized and reported.

For some diseases differences in reported occurrence are attributable to variations in the criteria for diagnosis or in the definition of cases.

An understanding of local and nation-

al programs is required to assess the possible effect of various factors on the data reported. For diseases with an appreciable case fatality some estimate of the degree of underreporting may be obtained by comparing the numbers of reported cases and registered deaths. Excessive ratios of deaths to cases are common in areas with substantial underreporting.

REPORTING AREAS

In some countries of the Americas reports on notifiable diseases other than the quarantinable ones are limited to a "reporting area". The reporting area may consist of those localities in which health services are available or of selected communities meeting certain requirements as to adequacy of reporting (communities reporting for every month of the year for instance). In 1963 there were five countries with reporting areas: Colombia, Honduras, Paraguay, Peru and Venezuela.

Population estimates for the reporting areas of these countries are given in Appendix Table B. The proportion of the total population included in the reporting areas in 1962 and 1963 is shown in Table I.

These proportions changed relatively little from 1962 to 1963. El Salvador for the first time in 1963 reported cases for the entire country; in previous years the data were

Table 1. Percentage of Population Included in Reporting Areas of Six Countries of the Americas, 1962 and 1963

Country	1962	1963
Colombia	92	94
El Salvador	58	.
Honduras	49	49
Paraguay	66	58
Peru	49	44
Venezuela	67	68

limited to a reporting area including about half the population.

Malaria is reported for the entire country in Honduras, Paraguay, Peru and Venezuela. In Peru and Venezuela rabies is also reported on a nationwide basis.

QUARANTINABLE DISEASES

By international agreement prompt reporting is required of all cases of the quarantinable diseases. In the Americas reports are made directly by national health services to both the Pan American Sanitary Bureau and Headquarters of the World Health Organization.

Five of the six quarantinable diseases viz. plague, louse-borne relapsing fever, smallpox, louse-borne typhus and yellow

fever occur in the Americas; the sixth, cholera, has not been present since 1911. In recent years louse-borne relapsing fever has occurred only sporadically in the Region and in 1963 no case of this disease was reported. The total number of cases of each quarantinable disease reported in the Americas during the last ten years is given in Table 2. The distribution by country of the cases reported in 1962 and 1963 is shown in Table 3.

Table 2. Reported Cases of Quarantinable Diseases in the Americas, 1954-1963

Year	Plague	Relaps-ing fever, louse-borne	Small-pox	Typhus, louse-borne	Yellow fever
1954	171	3	11 979	3 104	95
1955	87	38	8 348	1 545	39
1956	115	-	6 389	1 089	28
1957	154	-	6 220	747	80
1958	97	6	4 343	818	61
1959	93	10	4 763	659	30
1960	258	4	5 158	668	34
1961	308	1	8 175	474	82
1962	527	3	7 858	557	52
1963	423	-	6 431	465	141

a. Plague

The steady increase in reported cases which began in 1960 was interrupted in 1963, the annual total decreasing from 527 in 1962 to 423 in 1963. As in previous years plague remained centered principally in four South American countries: Bolivia,

Brazil, Peru and Ecuador (Figure 1). The decrease in 1963 occurred largely in Manabi Province, Ecuador, where 144 cases were reported as against 241 in 1962, and in the northern departments of Peru. Six cases occurred in Ancash Department, Peru, where plague had not been reported since

(a) Including one imported case.

(b) Including two imported cases.

(i) Imported.

1958. The 53 cases notified in Bolivia all occurred in an outbreak in an area of Santa Cruz Department; this department had been free of plague since 1960. In Brazil 39 cases were reported mainly in the Northeastern States. A single case occurring in the United States in New Mexico was infected in Arizona.

b. Smallpox

In Brazil revised totals for smallpox were reported for the years 1961, 1962 and 1963. These revisions were the result of special efforts to assemble data for additional areas including both state capitals and areas outside the capitals. The revised number of cases for 1963 was 5,516 while the new totals for 1961 and 1962 came to 7,656 and 7,589 cases respectively.

Brazil accounted for about 85 per cent of all notifications of smallpox in the Americas in 1963. Another 13.5 per cent were contributed by Peru. A retrospective investigation disclosed an epidemic in the Amazon region of Peru in 1963 and 865 cases were reported for that country which had been free of smallpox since the completion of a vaccination campaign in 1954.

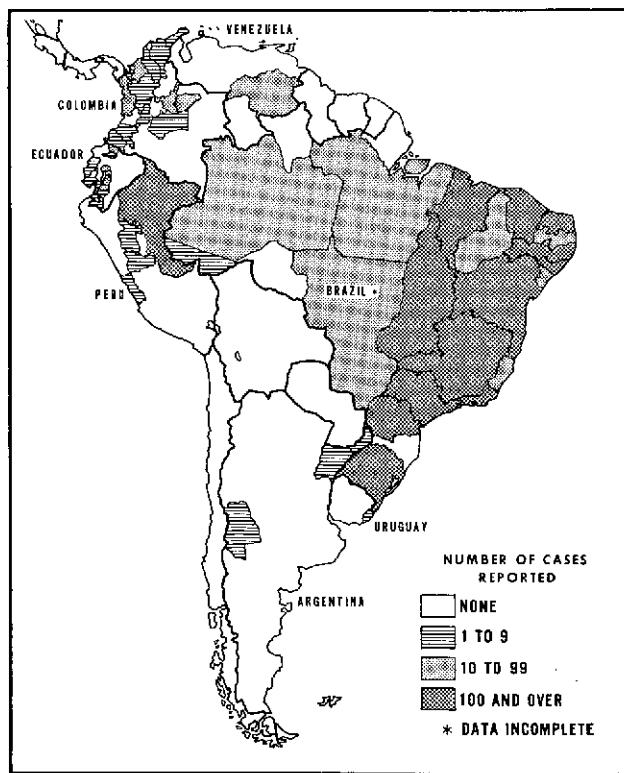

The retrospective investigation was initiated in Peru in December 1963 when four confirmed cases including two secondary cases were reported in hospitals in Lima. The two primary cases had contracted the disease in the Amazon region, one in Iquitos and the other in Pucallpa. Analysis of available records in the City of Iquitos showed that 861 cases of a febrile-eruptive syndrome chiefly of a pustular type had been observed in April-December 1963. The overall fatality rate for these cases was 7 per cent. For 104 cases who had been hospitalized the fatality rate reached 19 per cent. Initially these cases were diagnosed as chickenpox. On review the clinical symptoms were considered to be those of smallpox. During 1964 preliminary field studies revealed the presence of smallpox in different localities throughout much of the Peruvian Amazon region. It was concluded that a large-scale epidemic seemed to have started in Loreto Department in 1961 or possibly even earlier

The only other countries in the Americas reporting non-imported smallpox in 1963 were Colombia (4 cases), and Ecuador (45 cases). In both countries there has been a steady decrease in cases reflecting the effect of extensive vaccination programs. A single imported case was notified in Uruguay.

The concentration of cases of smallpox in Brazil and adjoining regions of Peru is illustrated in the map in Figure 2 which is based on notifications for the three years 1962-1964. Other countries affected during this period were Ecuador and Colombia and to a lesser extent Venezuela and Uruguay.

Figure 2

REPORTED CASES OF SMALLPOX BY MAJOR POLITICAL DIVISIONS OF EACH COUNTRY IN THE AMERICAS. THREE-YEAR PERIOD 1962-1964

Note: Excluding imported cases (Argentina 11, Canada 1, Uruguay 6).

No cases were reported in the countries not shown in this map.

c. Louse-borne Typhus

The general downward trend of this disease continued in 1963. During the year 465 cases were notified as compared to 557 in 1962 and 818 in 1958. The disease re-

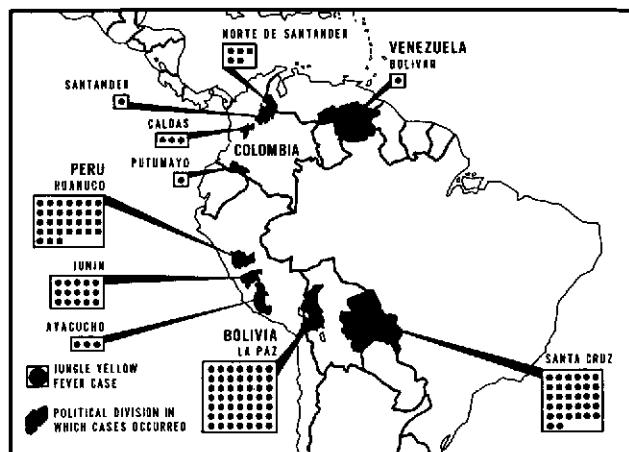

mained limited to the mountainous areas of Mexico and the Andean region of South America. A substantial increase in cases occurred in Bolivia, and Colombia reported cases for the first time since 1960.

d. Jungle Yellow Fever

In 1963 jungle yellow fever was reported in four countries in north and central parts of South America: Bolivia, Colombia, Peru and Venezuela (Figure 3). The total number of cases reported was markedly higher than in 1962, 141 as compared to 52. Outbreaks in jungle areas of Bolivia and Peru accounted for this increase. In Bolivia 49 cases were reported in La Paz Department and 32 cases in Santa Cruz Department. In Peru the outbreak in Huanuco Department which began in 1960 continued with 31 cases in 1963. In addition 3 cases were reported from Ayacucho Department and 15 from Junin Department. There was a reduction in reported cases in Colombia where ten cases were notified in three depart-

Figure 3

REPORTED CASES OF JUNGLE YELLOW FEVER BY MAJOR POLITICAL DIVISIONS OF EACH COUNTRY, AND LOCATION, IN THE AMERICAS, 1963

ments in 1963; in 1962 there were 30 cases distributed over large parts of the country. A single case occurred in Bolivar State, Venezuela, in December 1963; it was followed by two more cases in January 1964.

ARTHROPOD-BORNE VIRAL DISEASES

Activity of several of the arthropod-borne viruses was reported in the Americas in 1963 including widespread outbreaks of dengue in the Caribbean Islands and of encephalitis in Venezuela.

a. Dengue

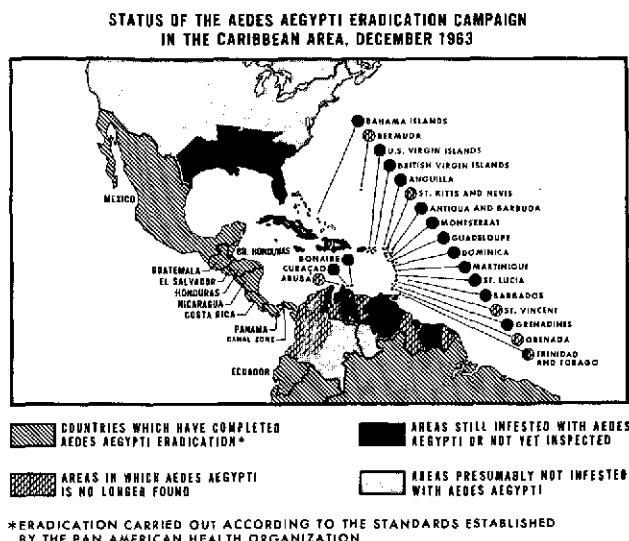

A series of outbreaks of dengue started in the Caribbean region in 1963 and continued into 1964. Jamaica, Puerto Rico, Martinique, Curaçao and Antigua were affected in 1963 and in the first half of 1964 the disease appeared in Anguilla, Dominica and five States of Venezuela.

Dengue is principally transmitted by the *Aedes aegypti* mosquito, which is also the vector of urban yellow fever. Campaigns aimed at the eradication of this vector have been conducted in the Americas with considerable success. In many parts of the Caribbean area, however, the vector has developed resistance to DDT and other chlorinated in-

secticides and the outbreaks of dengue in 1963 coincided with the interruption of eradication campaigns and increasing prevalence of the vector in this area. In the years preceding these outbreaks dengue was never entirely absent from the Caribbean region. In the Dominican Republic *Aedes aegypti* infestation as well as cases of dengue have been reported for many years and the disease is considered endemic in this country. In Venezuela dengue was notified in each of the years 1947-1960 but not in 1961-1963. The disease was also reported repeatedly from St. Kitts-Nevis and Anguilla - in 1951, 1952 and 1956. There were no further cases in these islands until the outbreak in 1964 in Anguilla. The islands of St. Kitts and Nevis have been free of *Aedes aegypti* since 1959.

The status of the *Aedes aegypti* eradication campaigns in the Caribbean area at the end of 1963 is shown in Figure 4 and the outbreaks of dengue in 1963 and 1964 in Figure 5.

Figure 4

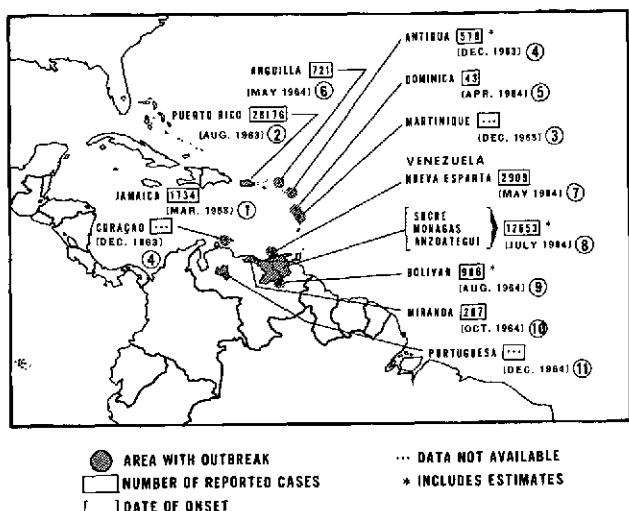

The first outbreak of dengue in 1963 occurred in Jamaica. Starting in Spanish Town in March the epidemic spread throughout the island reaching its peak in July-October. A total of 1578 cases was reported to the end of the year. Owing to the mild character of the disease reporting was incomplete. According to a survey conducted in the Kingston-St. Andrews area the attack rate was 2.6 per cent in July.

In August dengue appeared on the northcentral coast of Puerto Rico. An epidemic developed which swept around the island in a clockwise direction reaching the western coast in January 1964. Reported cases totalled 24,453 in 1963 with a maximum incidence in September-November. A survey in the town of Guaynabo showed an attack rate of about 36 per cent for the period August to mid-November.

During December outbreaks of dengue occurred on the islands of Antigua, Curaçao and Martinique, situated in widely separated sectors of the Caribbean. The number of cases in Curaçao and Martinique is not known; for the latter island the attack rate was estimated at about 2-3 per cent.

Figure 5

EPIDEMICS OF DENGUE IN THE CARIBBEAN AREA, 1963 AND 1964

b. Arthropod-borne Encephalitis

During 1963 outbreaks of arthropod-borne viral encephalitis were reported from Canada, the United States and Venezuela. Data on these outbreaks are summarized in Table 4.

In Venezuela a series of major outbreaks due to Venezuelan equine encephalitis started in May in Zulia State which had suffered a severe epidemic the previous year. The outbreaks spread eastward across the country reaching Sucre State in August. A total of 7,198 cases were reported from rural areas in eleven states. It is believed that the disease had long been endemic in most of these rural areas but had not been reported because of its generally mild non-specific symptoms. In addition to the human cases, 1,133 cases in equines were reported in 1963.

Across the border from Zulia State in the Commissary of La Guajira, Colombia, a marked concentration of cases of acute infectious encephalitis was observed in October. This area had been the site of an intense outbreak of Venezuelan equine encephalitis the previous year. Further details

of the cases reported in 1963 are not available but the possibility that they were due to arthropod-borne encephalitis cannot be excluded.

An outbreak of Western equine encephalitis occurred in the Province of Saskatchewan, Canada, in August-October. Thirty-eight confirmed human cases and 279 cases with 47 deaths in horses were reported.

Table 4. Cases of Arthropod-Borne Encephalitis Reported in Outbreaks in the Americas, 1963

Area	Begin-ning of outbreak	End of out-break	Number	
			Cases	Deaths
Canada (a)				
Province:				
Saskatchewan	20/VIII	31/X	38	3
United States				
State:				
Texas (b)	1/VII	15/X	45	-
Venezuela (c)				
States:				
Zulia	18/V	9/XI	762	5
Trujillo	16/VI	5/VIII	428	-
Cojedes	19/VII	23/VIII	13	3
Miranda	15/VIII	5/X	572	2
Portuguesa	25/VIII	21/IX	384	1
Falcon	18/VIII	2/XI	133	1
Aragua	19/VIII	8/IX	205	4

Sucre	25/VIII	28/XII	2447	9
Anzoátegui	1/IX	2/XI	527	8
Guarico	14/IX	9/XI	410	11

- (a) 36 cases confirmed serologically, 2 by virus isolation. Reported equine cases: 279 with 47 deaths.
- (b) Hale county and adjacent counties; 41 cases classified serologically as Western equine encephalitis, 4 as St. Louis encephalitis. Reported equine cases: 33.
- (c) Venezuelan equine encephalitis diagnosed serologically and by virus isolation. Reported equine cases: 1,133.

In the United States a single outbreak of arthropod-borne encephalitis was reported in Hale County and neighboring counties, Texas State, in July-October. During the outbreak more than 70 clinical cases were notified of which 41 were classified serologically as Western equine encephalitis. Among horses in the epidemic area 33 suspect cases were recorded.

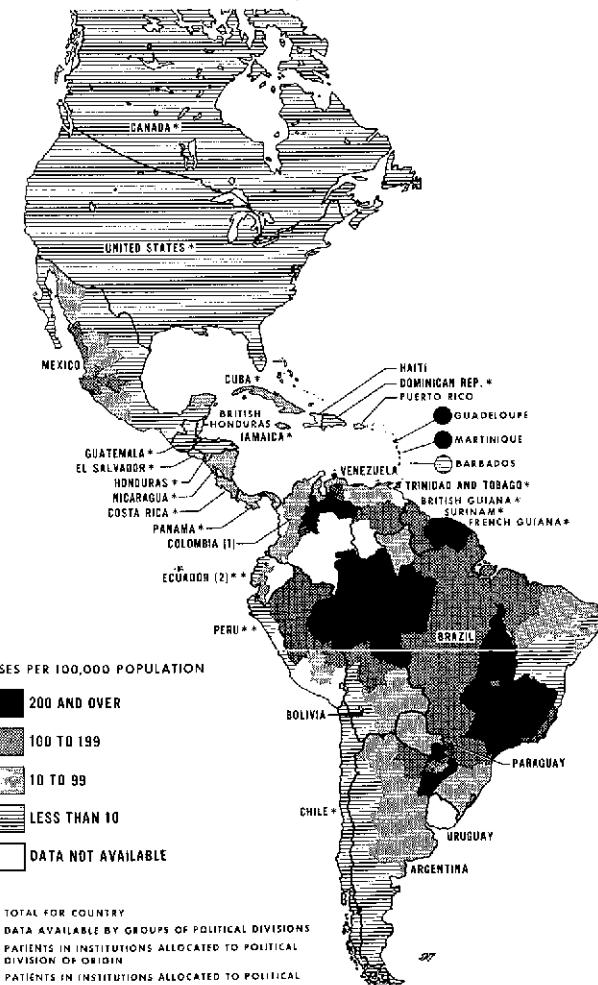

LEPROSY

Leprosy is present and reported in almost all countries and other areas of the Americas. In some areas of Middle America and in large parts of South America the disease is highly prevalent, constituting an important health problem.

In the map in Figure 6 the recorded prevalence of leprosy is shown by country and for the larger countries by major political divisions. The map is based mainly on data derived from national and local case registers. These data must be considered incomplete. In many areas, particularly the more remote rural areas, case-finding is in its initial stages and the known cases

Figure 6

PREVALENCE OF LEPROSY BY MAJOR POLITICAL DIVISIONS OF EACH COUNTRY IN THE AMERICAS, 1962 OR 1963

may represent only a fraction of the total. Deficiencies in the registration systems are another source of error.

As shown by the map the high prevalence rates, exceeding 100 cases per 100,000 population are largely concentrated in an area covering most of Brazil and parts of the neighboring countries. In several political divisions within this almost continuous area prevalence rates exceeding 400 cases per 100,000 population have been recorded. A limited area of relatively high prevalence is also observed in Middle America in the western part of Mexico.

At the end of 1963 there were over 167,000 cases on the active registers in 18

countries of Middle and South America. Information on these cases is summarized in Table 5. Only somewhat more than half of the registered cases were subject to periodic surveillance. Of the cases with clinical form reported, 45.4 per cent were classified as "lepromatous leprosy" the most infectious form of the disease. For some countries the clinical classification is reported separately for cases under surveillance and cases without surveillance. Thus in Paraguay, lepromatous leprosy was the diagnosis in 56.2 per cent of the cases under surveillance and in 23.8 per cent of those without surveillance. In Venezuela the corresponding figures were 44.7 and 38.5 per cent. It would seem that a substantial proportion

(a) Includes data for Jamaica and Trinidad and Tobago not included in the subgroups.

(b) All the country.

(c) Provinces of Entre Ríos, Misiones, and Tucuman, and Buenos Aires City.

(d) Included in preceding line, therefore not added to the totals.

(e) Data as of 30 September 1963.

(f) Incomplete data. (g) Data as of 31 December 1962.

of the cases without surveillance may be lepromatous. A definite excess in registered cases among males is observed in all but one of the 10 countries for which data by sex are available. Of the patients whose age is known 7.2 per cent were under 15 years of age; by country this proportion ranged from 11 to 1.8 per cent.

Twelve countries reported 262,818 registered contacts of whom 118,525 or 45 per cent were subject to periodic surveillance. In the same countries there were 127,203 registered cases. The number of contacts under surveillance per registered case was thus less than one. By country this ratio ranged from 0.5 to 4.1. This indicates that only a limited proportion of the

close contacts, a group with a relatively high risk of developing leprosy, are subject to periodic surveillance.

The total number of newly reported cases in the Americas for 1963 was 4,085. For 1962 the total reported cases were 3,229. Prior to 1962 close to 10,000 cases were notified each year. The reason for the low totals for 1962 and 1963 is that no data were available for Brazil in 1962 and only incomplete data in 1963. This country contributed about two-thirds of the cases reported annually in the Americas prior to 1962. Excluding Brazil, the number of reported cases per 100,000 population was highest in 1963 in French Guiana (222.9), Surinam (62.8), Paraguay (38.6) and Guadeloupe (19.2).

MALARIA

The campaign to eradicate malaria from the hemisphere made further progress during 1963, with many national eradication programs achieving such low levels of malaria prevalence in parts of their originally malarious area that these could be placed in the consolidation phase. In this phase no anti-malarial measures are taken on a mass scale but intense surveillance is maintained to discover and eliminate any residual foci of malaria. Areas in eleven countries, with populations totalling eight million persons, were added during 1963 to those already in this phase.

The territory in which eradication of malaria is claimed was also augmented during 1963 by the addition of new areas in Venezuela, of the last remaining part of the originally malarious area of Guadeloupe and of the first areas to be placed in maintenance in Peru.

There were also difficulties in some countries. In Central America and part of Mexico, the problem areas already delineated in which the vector, *A. albimanus*, is resistant both to dieldrin and to DDT increased only slightly, but within them little progress was made; alternative and supplementary methods of attacking malaria transmission are considerably more costly to

implement than the classic attack of semi-annual intradomiciliary spraying with DDT, and funds were not available to finance adequate campaigns. Financial troubles interrupted or limited operations in a number of other national campaigns as well - Bolivia, Honduras, Peru, Argentina and others.

A technical problem of a different nature handicapped the campaign in British Guiana, where a strain of *Plasmodium falciparum* resistant to chloroquine, which has been found in a district in the interior, has reduced the effectiveness of the medicated-salt program in operation and motivated a resumption of DDT spraying in the localities affected.

In Table 6 data for 1962 and 1963 on reported cases and on blood smears found positive by the national malaria eradication services are presented country by country. For several countries marked differences are observed between the two kinds of data. In those instances where the number of positive smears (confirmed cases) substantially exceeds that of reported cases insufficient coordination of the malaria eradication service with the reporting system of the general health services may be the cause. In some countries the opposite is observed,

notified cases of malaria exceeding the number of positive slides. This indicates that part of the cases notified are based on clinical diagnosis not confirmed by a blood-smear.

A considerable excess of positive slides over notified cases is observed for Bolivia. While the number of cases reported fell between 1962 and 1963 the number of

Table 6. Reported Cases of Malaria and Blood Smears Found Positive by Malaria Eradication Services in Countries and Other Areas of the Americas, 1962 and 1963

(a) Confirmed cases.

(b) Reporting area.

(c) Excluding 463 cases acquired outside the country.

positive slides increased. Clearly a large part of the positive cases detected by the eradication service are not included in the returns of the notifiable disease reporting system.

The data for Argentina, Costa Rica, Cuba, Panama and Peru indicate progress in reducing malaria: both reported cases and positive smears have decreased in number. The same is true for the Dominican Republic. In this country, however, the number of reported cases substantially exceeds that of positive smears.

In some instances the changes in reported cases and positive slides may not reflect changes in the frequency of malaria. In three countries in which only cases confirmed by positive slides are reported, Brazil, El Salvador and Surinam, apparent increases in malaria are observed during 1963. However, these may be due to the intensified case-finding activities of the eradication services in these countries. In Brazil and El Salvador in fact the proportion positive among the total number of slides examined decreased. Similarly the fall in malaria in Ecuador may be related in part to the reduced search for cases in the eradication program in that country.

In many areas of the Americas the malaria eradication campaigns are approaching their final phases and efforts are being made to integrate the eradication services with the general health services. An important objective of such integration is the development of a common system for the detection and reporting of the remaining cases. As the number of cases decreases their detection and reporting becomes increasingly important.

TUBERCULOSIS

The increased emphasis given to programs for the control of tuberculosis in Latin America has so far been reflected chiefly in the mortality from the disease. Reductions in the number of reported cases have been relatively moderate. One reason for this may be the more complete reporting resulting from intensified case finding.

Available data on the changes in tuberculosis mortality and morbidity in the Americas during the decade 1953-1962 are presented in Table 7, separately for Northern America, Middle America and a group of four countries in South America. There were marked reductions in deaths from tuberculosis between 1953 and 1962 ranging

Table 7. Reported Cases and Deaths from Tuberculosis with Rates per 100,000 Population in the Three Regions of the Americas, 1953 and 1962

Region	Cases				Deaths				Reported cases per death (a)	
	Number		Rate		Number		Rate			
	1953	1962	1953	1962	1953	1962	1953	1962	1953	1962
Northern America	94 038	59 599	54.1	29.1	21 568	10 291	12.4	5.0	4.4	5.8
Middle America	20 865	28 712	55.2	57.8	12 493	12 608	32.1	24.8	1.7	2.3
South America	41 267	47 728	230.5	188.6	8 729	8 954	42.3	32.0	5.4	5.9

Note: Data refer to 2 countries in Northern America, 6 countries and 7 other areas in Middle America, and 4 countries in South America.

(a) Ratios based on rates since areas of notification and death registration differed in 5 countries.

from 60 per cent in Northern America to about 25 per cent in the two other regions. Somewhat smaller declines in reported cases occurred in Northern America and South America; in Middle America reported cases showed a slight upward trend. The levels of morbidity and mortality in Latin America are high compared with those in Northern America. In 1962 both registered deaths and reported cases per 100,000 population were six times higher in South America. In Middle America registered deaths were about five times higher whereas reported cases were only twice as high. These relationships are illustrated by the ratio of reported cases to registered deaths, which is almost the same in Northern and South America - namely 5.8 and 5.9 respectively. In contrast in Middle America it is only 2.3. This low ratio points to substantial underreporting in this Region.

In 1962 registered deaths in the countries of the Americas ranged from 4.2 per 100,000 population in Canada to 72.1 in Peru (Table 8). Six Latin American countries had death rates exceeding 25 per 100,000. The number of cases reported by countries in 1963 varied from 445.7 per 100,000 population in Peru to 28.7 in the United States 22.3 in Nicaragua and 18.4 in Jamaica (Table I). There were eight countries, five in South America and three in Middle America, reporting over 100 cases per 100,000 population. Among the areas of the Americas other than the countries the range of death rates was from 2 to 31 and that of reported case rates from 2 to 230.

(f) Data for 1961.

A comparison by age groups of annual reported case rates for 1961-1963 in four selected countries is presented in Figure 7. The curves for case rates for the two South American countries, Peru and Colombia, run far above those for the United States and Jamaica at all ages. The greatest differences between the two upper curves and the two lower ones are observed under 35 years of age and the smallest over 45 years. In Peru the age specific rates are highest at ages 15-24 years, in Colombia at ages 25-44 years, and in Jamaica at ages 45-64 years while in the United States they reach their maximum only in the oldest age group. It would appear that the higher incidence of reported cases in Latin American countries compared with the United States or Jamaica

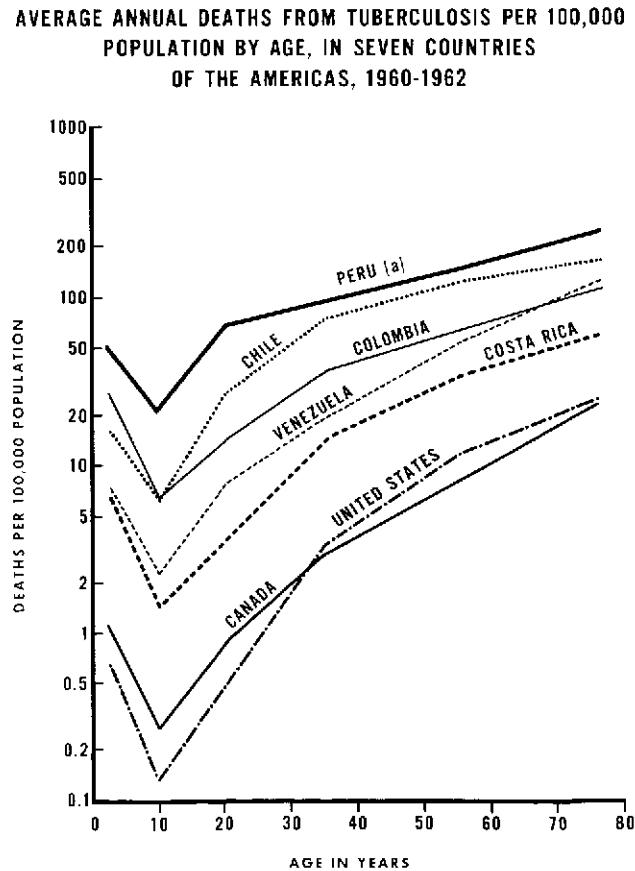

Figure 7

reflects, in part, relatively high infection rates at younger ages.

Annual death rates by age groups for 1960-1962 are shown in Figure 8 for seven selected countries. The mortality curves present a relatively uniform pattern with a minimum at ages 5-14 followed by a continuous increase. The death rates of the Latin American countries are higher at all ages than those of the United States and Canada with the greatest differences occurring in the younger age groups. A comparison of Peru and Colombia with the United States reveals differences in death rates far exceeding those observed in reported case rates, the excess being most marked at younger ages. This may point to under-reporting of cases as well as higher case fatality rates in the Latin American countries.

Figure 8

The general reduction in deaths from tuberculosis observed in the Americas is analyzed by sex and age for selected countries in Figure 9. In each of the six countries included the greatest decline is in the

younger age groups irrespective of sex. In general the female excess mortality at ages 15-24 has decreased and the male excess mortality at higher ages increased.

(a) Data for typhoid fever include data for paratyphoid fever, in Argentina, Brazil, Canada, Chile (except in 1962), Colombia, Ecuador, Honduras in 1963, Paraguay, Peru, Venezuela, Antigua, Dominica, Martinique, and St. Lucia in 1963.

(b) Respiratory tuberculosis (001-008)

(c) Data for State of Guanabara and capitals of 19 other states.

(d) Data for Federal District, States of Guanabara and Pernambuco, and capitals of 10 other states.

(e) Newly reported active cases.

(f) Reporting area except for louse-borne typhus.

(g) Reporting area.

(h) Including other salmonella infections (042).

TABLE B. ESTIMATED POPULATION OF REPORTING AREAS IN SIX COUNTRIES OF THE AMERICAS, 1963

Country	Population	Country	Population
Brazil (a)	15,371,000	Paraguay	1,100,000
Colombia	14,140,000	Peru	4,815,000
Honduras	1,000,000	Venezuela	5,526,000

(a) Reports received from the Federal District, States of Guanabara and Pernambuco, and capitals of 10 other states not treated as a reporting area.

INDEX

	Page	Page	
Aëdes aegypti eradication, status of	6,7	Filariasis, cases of	25
Age, cases by, diphtheria	33	deaths from	50-52
dysentery, all forms	33	Food poisoning, other, deaths from	50-52
encephalitis, acute infectious	33,34	Gonococcal infection, cases of	17
gonococcal infections	34	by age	34
hepatitis, infectious	34,35	deaths from	50-52
influenza	35	Hepatitis, infectious, cases of	17
leprosy	35	by age	34,35
malaria	35,36	by month	28
measles	36	deaths from	50-52
meningococcal infections	36,37	Hydatidosis, cases of	25
poliomyelitis, acute	37	in animals	48
scarlet fever	37	deaths from	50-52
syphilis	38	Infectious hepatitis (see hepatitis, infectious)	
tetanus	38	Influenza, cases of	18
tuberculosis, all forms	38,39	by age	35
typhoid fever	39	deaths from	50-52
whooping cough	40	Jungle yellow fever (see yellow fever)	
yaws	40	Leishmaniasis, cases of	25
deaths by, tuberculosis	13,14	deaths from	50-52
Amebiasis, cases of	15	Leprosy, cases of	10,18
by month	27	by age	35
deaths from	50-52	by political divisions	41,42
Ankylostomiasis, cases of	15	in active register	8-10
deaths from	50-52	by political divisions	8
Anthrax, cases of	15	deaths from	50-52
in animals	48	Leptospirosis, cases of	25
deaths from	50-52	in animals	48,49
Botulism, deaths from	50-52	deaths from	50-52
Brucellosis, cases of	16	Malaria, cases of	10,11,18
in animals	48	by age	35,36
deaths from	50-52	by month	28,29
Chagas' disease (see trypanosomiasis)		by political divisions	43-45
Chickenpox, deaths from	50-52	confirmed by bloodsmear	10,11
Deaths from communicable diseases	50-52	deaths from	50-52
tuberculosis	11-14,50-52	Measles, cases of	19
Dengue, cases of	25	by age	36
epidemics of	6,7	by month	29
Diphtheria, cases of	16	deaths from	50-52
by age	33	Meningococcal infections, cases of	19
by month	27,28	by age	36,37
deaths from	50-52	deaths from	50-52
Dysentery, cases of, amebic (see amebiasis)		Months, distribution by, amebiasis	27
bacillary, other and unspecified	16	diphtheria	27,28
by age	33	hepatitis infectious	28
deaths from	50-52	malaria	28,29
Encephalitis, acute infectious, cases of	17	measles	29
by age	33,34	poliomyelitis	30
arthropod-borne	7,8,48	typhoid fever	30,31
in animals	48	whooping cough	31,32
deaths from	50-52		
Erysipelas, deaths from	50-52
